Abstract

Retinal ganglion cells (RGCs) relay visual information from the eye to the brain. RGCs are the first cell type generated during retinal neurogenesis. Loss of function of the transcription factor *Atoh7*, expressed in multipotent early neurogenic retinal progenitor cells, leads to a selective and essentially complete loss of RGCs. Therefore, *Atoh7* is considered essential for conferring competence on progenitors to generate RGCs. DNA binding sites analysis of *Atoh7* using the Cut&Run method demonstrates that *Atoh7* directly targets genes controlling RGC specification. Despite the important function of *Atoh7* in RGC specification, when apoptosis is inhibited in *Atoh7*-deficient mice by loss of function of *Bax*, only a modest reduction in RGC number is observed. Single-cell RNA-Seq of *Atoh7*;*Bax*-deficient retinas shows that RGC differentiation is delayed, but that the gene expression profile of RGC precursors is grossly normal. *Atoh7*;*Bax*-deficient RGCs eventually mature, fire action potentials, and incorporate into retinal circuitry, but exhibit severe axonal guidance defects. This study reveals an essential role for *Atoh7* in RGC survival and demonstrates *Atoh7*-independent mechanisms for RGC specification.

Primary Reader and Advisor: Samer Hattar

Secondary Reader: Haiqing Zhao

Acknowledgements

I am eternally grateful for Samer Hattar, PhD. Samer's guidance and training will be with me for the rest of my life. Samer gave me agency to realize who I am by allowing me to take the long and hard path to my eventual success. Samer has made me fall in love with the Retina as a model system for all of neuroscience, as well as the field of Circadian Biology. Samer supported me as I learned from my failures and drove me to take complete ownership of my project and kept me well fed throughout my PhD.

As a member of the Mouse-Tri-Lab at Johns Hopkins university, while Samer was my official mentor, I was lucky to have Haiqing Zhao, PhD and Rejji Kuruvilla, PhD as co-mentors throughout my training. Samer, Haiqing, and Rejji are almost a superhero group, with each providing phenomenal guidance on their own, but together their mentorship and training is second to none. The Mouse-Tri-Lab has also provided me with a close knit group of colleagues with a wide variety of expertise. This style of collaboration and cooperation is something I would suggest to anyone doing research.

There is no amount of thanks I can give to the members of the Hattar lab that guided me through my first few years of graduate school, and who taught me everything I know how to do in lab; Alan Rupp, PhD, Bill Keenan, PhD, Diego Fernandez, PhD, Kylie Chew, PhD, Michael Thompson, PhD, and Tiffany Schmidt, PhD. Tiffany, a Post-doc in the Hattar lab when I joined, was a second mentor to me, and continues to be even after she started her own lab at Northwestern. Tiffany took me under her wing, and together we laid the foundation of what would become my entire thesis project.

Acknowledgements

My thesis work would not have been possible without the help of many labs around the world, who have provided countless guidance, advice, criticism, and expertise in their sub fields, many of which contributed data that was paramount to my thesis including; Brian Clark, PhD, Seth Blackshaw, PhD, Tudor Badea, PhD, Hope Shi, PhD, Tom Glaser, PhD, Joshua Singer, PhD, Thomas Kim, PhD, Michel Fries, Michel Cayouette, PhD, and many more from those who merely listened to my poster presentation to those who I have had lengthy discussions with.

I would also like to thank Joan Miller, the entire Biology office staff, the CMDB program, the mouse facility staff and in particular John Hayes and Ed Baker.

And thanks to Baltimore for becoming for welcoming us in and being kind, generous, genuine, weird, funky, and a whole lot of fun.

Dedication

This thesis is dedicated to Jui-Ko Chang, my partner in life and science, my sister Kayla Kommit, and my parents Kathy Kommit and Michael Brodie for helping me to achieve my dreams in life and providing me with endless love and support.

Chapter 1 - Introduction

1.1 Light and retina

Light impacts many physiological functions including vision, circadian rhythms and sleep. In mammals, the retina is the only gateway for light information to reach the brain. The retina has been a model system for understanding developmental neurobiology for almost 2 centuries. The retina has six major classes of neurons and one major glia that develop from a common progenitor cell pool, whose multipotency diminishes over time, using a temporally ordered expression of transcription factors. Of the six neuronal classes, retinal ganglion cells (RGCs), the only projection neurons from the retina to the brain, are the first to develop, and are the main focus of this thesis. The RGCs are quickly followed in an overlapping manner by Cones, Horizontal cells and Amacrine cells. A little later Rods start to develop followed by Bipolar cells and lastly Müller glia (Carter-Dawson & LaVail, 1979; Clark et al., 2019; J. W. Hinds & Hinds, 1979; Rapaport, Wong, Wood, Yasumura, & LaVail, 2004; Sidman, 1960; Young, 1985).

1.2 *Transcribing the Retina*

The retina has been a model system for understanding developmental neurobiology for almost 2 centuries. The retina is formed through a process of evagination to form the optic vesicle, invagination to form the optic cup, and proliferation and diversification to form the neural retina. The optic vesicle forms at around e8.25-8.5, though a bilateral evagination of the anterior neural plate. The cells that become the optic vesicle in the anterior neural plate are determined through combinatorial and sequential

expression of the eye field transcription factors (EFTF), specifically the **Lhx2** (LIM homeodomain), **Rax** (Retina and anterior fold homeobox), **Pax6** (Paired box), and **Six3** (Sine oculis homeobox). Lhx2 and Rax are the first of the EFTFs to be expressed in anterior neural plate at e7.5. In the Lhx2 knockout eye, development arrests between the optic vesicle and optic cup stage, the expression of all the other EFTFs is significantly reduced and also delayed, suggesting that Lhx2 controls expression of Rax, Pax6, and Six3 (Furukawa, Kozak, & Cepko, 1997; Tétreault, Champagne, & Bernier, 2009). Rax null mice fail to form an optic vesicle, suggesting that while Rax is downstream of Lhx2 it is instrumental in the evagination of the anterior neural plate into the optic vesicle (Furukawa et al., 1997; Mathers, Grinberg, Mahon, & Jamrich, 1997). Pax6 expression begins at e8.0 and Pax6 null mice have the same phenotype as the Lhx2 null mice with the eye development arresting between the optic vesicle and optic cup stage, however expression of the other EFTFs are unaffected, revealing that Pax6 expression is functionally downstream of Rax, Lhx2, and Six3 (Bernier, Vukovich, Neidhardt, Herrmann, & Gruss, 2001; Grindley, Davidson, & Hill, 1995). Six3 is expressed at e8.5 and in a conditional eye field knockout of Six3 the neural retina fails to form, arresting at optic vesicle stage, but the retinal pigmented epithelium continues to be specified and forms. In this conditional knockout of Six3 the optic vesicle normally expresses Rax, Lhx2, and Pax6 (W. Liu, Lagutin, Swindell, Jamrich, & Oliver, 2010; Oliver et al., 1995).

While all of the EFTF genes are necessary for optic cup formation, most are also sufficient to induce ectopic eye formation. Pax6 is well known to form ectopic eyes on the antennae, wings, and limbs of *Drosophila melanogaster* (Halder, Callaerts, &

Gehring, 1995). When Rax was overexpressed in both *Xenopus* and Teleost ectopic retinal tissue was formed (Chuang & Raymond, 2001; Mathers et al., 1997). Ectopic Six3 expression in *Drosophila* and in Murine models lead to ectopic retinal vesicle formation (Lagutin et al., 2001; Seimiya & Gehring, 2000). This analysis has not been done for Lhx2.

Pax2, a family member of Pax6, is expressed starting at E9 in the optic vesicle and plays an important role in both optic cup formation and axon guidance. Pax2 is expressed in the optic ventricle early, and a little later there is expression in the optic disk, and all along the optic stalk (NORNES, DRESSLER, KNAPIK, DEUTSCH, & Gruss, 1990). Pax2 is required for closure of the optic fissure to form the optic cup and in Pax2 null mice all RGCs project ipsilaterally (Torres, Gómez-Pardo, & Gruss, 1996). When Pax6 family members Pax2 or Pax6 spliceform Pax6(5a) replaced the coding region of Pax6, neither were sufficient to rescue the Pax6 null retinal development deficit. However, when Pax2 replaced the Pax6 coding region, the residual optic vesicle expressed Sox2 and Crx, but not Mitf, suggesting that Pax2 can partially compensate for some Pax6 functions, but not enough to complete optic cup formation or RPE formation (Carbe et al., 2013).

1.2.1 Optic Vesicle to Optic Cup Transition

In the optic vesicle, expression of **Mitf** (bHLH) begins around E9.0 and is throughout the entire optic vesicle and then very shortly thereafter **Vsx2**(Chx10)(Prd-L Homeodomain family) is seen to be expressed in the region of the optic vesicle that will

become the neural retina(distal/ventral optic vesicle), while *Mitf* expression is then downregulated in what will become the neural retina, while it is maintained in what will become the retinal pigmented epithelium (RPE) (dorsal optic vesicle) (Fuhrmann, 2010; LIU et al., 1994; Nguyen & Arnheiter, 2000). *Lhx2* is required for proper regionalization of the optic vesicle by controlling the expression of *Mitf* and *Vsx2* in collaboration with FGF signaling from either the lens ectoderm or the optic vesicle itself (Cai, Feng, & Zhang, 2010; Fuhrmann, 2010; Tétreault et al., 2009; Yun et al., 2009). *Lhx2* also controls the expression of **Six6** expression in the neural retina, which is important for regulating the early proliferation of the retinal progenitors into the early born retinal cell types (X. Li, Perissi, Liu, Rose, & Rosenfeld, 2002; Tétreault et al., 2009). The proliferative state of RPCs is controlled by the mouse homolog of **Meis1** and **Meis2** in both *Drosophila* and *Gallus* (Bessa et al., 2008; Heine, Dohle, Bumsted-O'Brien, Engelkamp, & Schulte, 2008).

As the optic vesicle matures, it eventually makes contact with the surface ectoderm. Once contact is made, the surface ectoderm begins to form the lens placode and the optic vesicle receives an unknown signal from the lens placode, which includes something more than just FGF, this signal is responsible for inducing the regionalization of the optic vesicle into neural retina. Following the induction of *Vsx2* expression in the optic vesicle, both the retinal and lens placodes invaginate. However, both the invagination and the lens placode tissue, post induction, is unnecessary for proper optic cup differentiation (Hyer, Kuhlman, Afif, & Mikawa, 2003; A. N. Smith, Miller, Radice, Ashery-Padan, & Lang, 2009).

1.2.2 Retinal Ganglion Cell Development and **Atoh7**

The retina consists of six retinal neuronal types and one glial type, which arise from a common progenitor pool, whose multipotency diminishes over time. It is a temporally ordered process starting with Retinal Ganglion Cells (RGCs) and ending with Müller glia and takes almost three weeks to complete in mice (Carter-Dawson & LaVail, 1979; J. W. Hinds & Hinds, 1979; Rapaport et al., 2004; Sidman, 1960; Young, 1985). Pax6 is required for optic cup formation, but it is also required later in retinal development to allow for the retinal progenitor cells (RPCs) to acquire their multipotency and different retinal fates. This is presumably due to Pax6's direct control over retinogenic bHLH factor expression, like **Atoh7** (atonal homolog 7), also known as Math5 (mammalian atonal homology 5), a basic helix-loop-helix transcription factor (Marquardt et al., 2001).

RGC development in mice has been shown to require **Atoh7** (N. L. Brown, Patel, Brzezinski, & Glaser, 2001; Jarman, Grell, Ackerman, Jan, & Jan, 1994; S. W. Wang et al., 2001). Atoh7 is conserved across many species from Humans (ATOH7) to Zebrafish (Atoh5) and distantly to Drosophila (atonal). Atoh7 mutant mice and zebrafish lack 95% of RGCs (N. L. Brown et al., 2001; Brzezinski, Prasov, & Glaser, 2012; Kay, Finger-Baier, Roeser, Staub, & Baier, 2001; S. W. Wang et al., 2001) and they: (1) have almost no visible optic nerve or functional connections from the retina to the brain (Brzezinski et al., 2005; Wee, Castrucci, Provencio, Gan, & Van Gelder, 2002); (2) lack proper retinal vasculature (Edwards et al., 2012); (3) show an increase in apoptotic cells in the retina

across embryonic development (L. Feng et al., 2010; Prasov & Glaser, 2012b); and (4) show an increase in cones and amacrine cells as well as a small decrease in the numbers of rods, Müller glia, and bipolar cells compared to wildtype (N. L. Brown et al., 2001; Brzezinski et al., 2005; Hufnagel, Le, Riesenberger, & Brown, 2010; S. W. Wang et al., 2001).

In *Drosophila* *atonal* is necessary for the first born and organizing photoreceptor, the R8 photoreceptor. Other photoreceptors do not require *atonal*, but do require the R8 photoreceptor for their local recruitment and development (Jarman et al., 1994).

Homozygous or hemizygous mutants for *atonal* are practically eyeless and what is left contain no photoreceptors. *atonal* mutants also secondarily have atrophy and apoptosis in the imaginal eye disk due to lack of photoreceptor formation. *atonal* also acts as the proneural gene for chordotonal organs and thus mutants lack adult and embryonic chordotonal organs (Jarman, Grau, Jan, & Jan, 1995). There are eight *atonal*-related bHLH genes in the mouse; *Atoh7*, *Math1* (*Atoh1*), *Ngn1*, *Ngn2*, *Ngn3*, *Neurod1*, *Neurod6*, *Neurod4*, *Ascl1*. In the mouse *Atoh7* is required for the development of RGCs, the first-born cell type in the retina. In *Atoh7* mutant mice, not only is there is a 95% reduction in RGC numbers, but no substantial amount of RGCs are seen at any timepoint in development, from E11 until P0 (N. L. Brown et al., 2001; L. Feng et al., 2010; S. W. Wang et al., 2001).

Atoh7 in mouse is only expressed in the developing retina and mature central auditory system (Saul et al., 2008), and in the retina is transiently expressed in neurogenic retinal progenitors cells from embryonic day 11 (E11) through birth (P0) with

a peak of expression at E14 (N. L. Brown et al., 1998; Clark et al., 2019; Kiyama et al., 2011; Prasov & Glaser, 2012a; S. W. Wang et al., 2001) , closely matching the observed birthdates of RGCs (Rapaport et al., 2004; Sidman, 1960; Young, 1985).

In the central auditory system Atoh7 is expressed in the globular and small spherical bushy cell of the VCN (ventral cochlear nucleus), as early as E12. In contrast to the retina, it is solely expressed by post-mitotic cells. This Atoh7 expression is maintained in adulthood in these VCN neurons and in its absence the cells are still present, but their morphology and firing patterns are diminished. Thus Atoh7 in these VCN neurons play a cell-autonomous role in the function of these neurons, which is in contrast to the proposed role and expression pattern of Atoh7 in the retina. The utilization of Atoh7 in these VCN neurons is also in contrast to the use of, closely related, Math1 in the development of these neurons, which is required for the development of all neurons of the caudal rhombic lip that migrate along the cochlear extramural stream (Saul et al., 2008; V. Y. Wang, Rose, & Zoghbi, 2005a).

1.2.2.1 Expression of Atoh7

Atoh7 has complex and temporally regulated expression in retinal development. During the first half of RGC development (E10.5-E14.5), Atoh7 seems to drive cell cycle exit as retinal progenitor cells (RPCs) that express Atoh7 during late S or G2, symmetrically divide into two RGCs (Brzezinski et al., 2012; L. Feng et al., 2010; Kiyama et al., 2011; Pacal & Bremner, 2014; Prasov & Glaser, 2012a; Wu, Sapkota, Li, & Mu, 2012). The expression of Atoh7 it is not always sufficient, however, to drive cell

cycle exit since ectopic expressing of Atoh7 does not always lead to cell cycle exit, depending on the cellular context of this expression (Le, Wroblewski, Patel, Riesenber, & Brown, 2006; X.-M. Zhang, Hashimoto, Tang, & Yang, 2018). After E14.5, Atoh7 is expressed later in the terminal cell cycle after terminal M phase (Brzezinski et al., 2012; L. Feng et al., 2010; Pacal & Bremner, 2014; Prasov & Glaser, 2012a), but is then turned off shortly after the completion of cell cycle (G0) and the migration to the ganglion cell layer (GCL) (L. Feng et al., 2010; Pacal & Bremner, 2014). In zebrafish, atoh7 is expressed during G2-phase of the terminal division to produce at least one RGC. There is also feedback regulation in zebrafish, as atoh7-expressing RPCs transplanted into a mutant environment lacking RGCs were 4 times more likely to divide symmetrically to give rise to two RGCs (Poggi, Vitorino, Masai, & Harris, 2005). This shows that while determination and development of RGCs is largely cell-intrinsic, extrinsic factors also modulate this process (Mu, Fu, Sun, Liang, et al., 2005b).

PAX6, NGN2, and RBPJ can all directly bind to the conserved primary enhancer of Atoh7 and regulate its expression. PAX6 is a positive regulator of both NGN2 and ATOH7. NGN2 is a positive regulator of Atoh7 expression. RBPJ can bind to Atoh7 at four distinct CSL sites, allowing it to more specifically control expression of Atoh7. The four sites of binding allow RBPJ to prime the Atoh7 locus to allow for its future expression, directly repress the expression of Atoh7, and for canonical Notch pathway suppression. The site of RBPJ-mediated priming of the Atoh7 locus is directly in-between the Pax6 binding site and a NGN2 binding site. In at least chickens (Cath5) and zebrafish (Ath5), ATOH7 also directly regulates its own transcription by binding

approximately 2kb upstream from its coding sequence and enhancing a positive feedback loop, however, this self-regulation might be specific to chicken and Zebrafish Atoh7. All of these factors work together to help drive the very pulsatile expression of Atoh7 (Del Bene et al., 2007; Hufnagel et al., 2010; Le et al., 2006; Miesfeld et al., 2018; A. N. Riesenberger, Le, Willardsen, Blackburn, Vetter, et al., 2009a; A. N. Riesenberger, Liu, Kopan, & Brown, 2009b; Skowronska-Krawczyk, Ballivet, Dynlacht, & Matter, 2004; Souren, Ramon Martinez-Morales, Makri, Wittbrodt, & Wittbrodt, 2009; Willardsen et al., 2009).

1.2.3 Retinal Ganglion Cell Development – Parallel to and downstream of Atoh7

A family of transcription factors downstream of Atoh7 is the Pou-domain family **Brn3a**(Pou4f1), **Brn3b**(Pou4f2), and **Brn3c**(Pou4f3), all three are expressed in development and also through adulthood. Brn3b starts to be expressed at E11.5 in the migrating RGCs in the neuroblast layer of the retina, and then at E12.5 Brn3a expression was seen only in the ganglion cell layer (Badea, Cahill, Ecker, Hattar, & Nathans, 2009; Mu, Fu, Sun, Beremand, et al., 2005a; L. Pan, Yang, Feng, & Gan, 2005). These are expressed in partially overlapping populations during development and also throughout adulthood. During development they are expressed in 80%, 80%, and ~50% of all RGCs respectively. In the adult 81.6% of RGCs are Brn3a positive and approximately 55% of RGCs are Brn3b positive with even fewer being Brn3c positive. In the adult retina 87% of Brn3a positive RGCs express Brn3b and 78% of Brn3b positive

RGCs express Brn3a. The overlapping expression of Brn3c and the other two Pou-domain family members is approximately 80% as well (Badea et al., 2009; Rodriguez, de Sevilla Müller, & Brecha, 2014; Xiang et al., 1995). Brn3b is required for 70% of RGCs developmental survival, commitment to RGC fate, proper dendritic arbor size, proper inter-retinal axon guidance, and proper brain projections (Badea et al., 2009; Badea & Nathans, 2011; Erkman et al., 1996; Gan, Wang, Huang, & Klein, 1999; Gan et al., 1996). Brn3b is first expressed in late G2/S phase of RPCs in mouse and humans, partially coincident with Atoh7 (L. Feng et al., 2010; Pacal & Bremner, 2014). Interestingly, Brn3a is sufficient to rescue the Brn3b knockout phenotype when placed under control of the Brn3b promoter (L. Pan et al., 2005). Brn3a null mice do have a slightly reduced RGC number, increase in number of bistratified RGCs, and improper dendritic arbor formation (Badea et al., 2009; M. Shi et al., 2013). Brn3c null mice do not have any significant defects, however, Brn3c knockout exacerbates the Brn3b knockouts phenotype with only 13% of wildtype RGC numbers remaining (S. W. Wang et al., 2002). In a Atoh7 null retina, there are only 5% of wildtype RGC numbers, but these remaining RGCs have been seen to express Brn3a, Brn3b, and Islet1, suggesting that while they may be downstream of Atoh7 (Mu, Fu, Sun, Beremand, et al., 2005a; Wu et al., 2015), they can also be activated independently (Hufnagel et al., 2013; Prasov & Glaser, 2012b; S. W. Wang et al., 2001; Wu et al., 2015).

Brn3b has been shown to complex with **Isl1** (Islet1, Lim-homeodomain family), which is also downstream of Atoh7 (R. Li et al., 2014; Mu, Fu, Sun, Beremand, et al., 2005a). Isl1 is expressed at E11.5 in a mostly overlapping population with brn3b in

RGCs, and after E15 it is also expressed in amacrine cells and bipolar cells. In RGCs, from E11 until E13.5 Brn3b and Isl1 have been seen to be co-expressed during late S or G2, however after E15, their expression is seen only in post-mitotic RGCs (Prasov & Glaser, 2012a). A conditional Isl1 knockout leads to defects in bipolar cells, amacrine cells, and RGCs (Elshatory et al., 2007; Rachel et al., 2002). Developmentally, the numbers of RGCs are unchanged in the knockout until E17.5, when RGC specification defects started to arise. By P7 28% of wildtype RGC numbers were seen and by P15 5% of wt RGC numbers were seen, suggesting its role is in the maintenance, differentiation, and survival of RGCs and not their specification (Mu, Fu, Beremand, Thomas, & Klein, 2008). In the adult retina all RGCs, On-bipolar cells, and cholinergic amacrine cells express Isl1. However, a related family member **Isl2** (Islet2) is expressed starting at E13.5 in RGCs and is continued to be expressed in 30-40% of adult RGCs. Isl2 is shown to be expressed only in contralateral projecting RGCs and in Isl2 null mice there is a significant increase in ipsilaterally projecting RGCs, and no decrease in developmental RGC numbers (Elshatory et al., 2007; Pak, Hindges, Lim, Pfaff, & O'Leary, 2004). The effect of Isl2 on survival through development of RGCs is unknown since no conditional mutant exists and Isl2 null mice die at P0.

Brn3b controls the expression of **Tbr2** (Eomes, T-box brain 2) in a subset of Brn3b positive RGCs starting at E14.5. In a retinal specific Tbr2 knockout there is a 30% reduction in RGC numbers (Mao, Kiyama, Pan, Furuta, Hadjantonakis, et al., 2008b). One role of Tbr2 is to specify a unique RGC subtype that express melanopsin making them intrinsically photosensitive RGCs (ipRGCs) as well as a population that have the

ability to express melanopsin. In the retinal specific *Tbr2* knockout there are no ipRGCs detectable, and *Tbr2* expression allows RGCs to become ipRGCs upon reduction of current ipRGC numbers (Mao et al., 2014). Other rolls for *Tbr2* in RGC development are unknown. Another family member ***Tbr1*** was shown to be directly downstream of *Atoh7* (ChIP verified), although its role is unknown (Mao et al., 2013).

Oct1 and **Oct2** (Onecut family) are transcription factors expressed starting at E11.5 in both the neuroblast layer as well as the ganglion cell layer. Oct1&2 are both independent of *Atoh7*, *Brn3b*, and *Isl1* for expression (Wu et al., 2012). In a retinal specific Oct1 knockout there is an 80% decrease in horizontal cell (HC) numbers, however the rest of the retina seems normal. A similar phenotype is seen for the Oct2 retinal specific knockout which has a 50% decrease in HCs. However, in an Oct1/Oct2 retinal specific double knockout there were no HCs, a 30% reduction in RGC numbers, 30% reduction in cone numbers, 32% reduction in amacrine cell numbers and 16% reduction in bipolar cell numbers. These decreases in cell numbers was not due to an increase in apoptosis suggesting that they are involved in the development of these cells and not their survival (Sapkota et al., 2014; Wu et al., 2013). Thus, Oct1 and Oct2 have compensatory functions in the single knockouts, but combined have a profound role in the development of horizontal cells, cone cells, RGCs, and amacrine cell development. Thus, Oct1 and Oct2 might be involved in a *Atoh7*-independent RGC developmental program.

Dlx2 (Distal-less homeobox) and **Dlx1** are both expressed in the neural retina during retinogenesis. *Dlx2* is expressed beginning at E11.5 and its expression is seen

through adulthood in the GCL, amacrine cells, and horizontal cells, while *Dlx1* is expressed at least at E12.5 and it is unknown if it is expressed at E11.5. It is expressed in the GCL and is downregulated after development. *Dlx1&2* redundancy is seen elsewhere in the forebrain so was not analyzed in the retina. However, in a *Dlx1/Dlx2* null mouse there is a 34% decrease in RGC numbers seen only after E16.5, and no abnormalities were seen in other retinal cell types in the double mutants at least before birth since these animals die at birth. There is also a loss of late born RGCs in the double mutant. The double mutant also showed signs of increased apoptosis of RGCs between E13.5 and E18.5, suggesting *Dlx1&2* play a role in the survival or terminal differentiation of these RGCs. The authors suggest *Dlx1&2* might play a role in late born RGCs in a *Atoh7* independent manner while play a parallel role in early born RGCs, however there is some weak evidence that *Dlx1&2* are downstream of *Atoh7*, and that *Dlx1&2* activity is inhibited through direct protein-protein interaction with *Brn3b* (de Melo et al., 2005; 2007; Eisenstat, Liu, Mione, & Zhong, 1999; L. Feng et al., 2011).

Barhl2 (Bar-class homeodomain) is first expressed at E13.5, however its expression during development is seen only in post-mitotic cells, and in the adult it is expressed in all amacrine cells, all horizontal cells, and 33% of RGCs. Forced overexpression of *Barhl2* beginning at P0 leads to increase in amacrine cell numbers and a decrease in bipolar cells and müeler glia cells. A *Barhl2* null retina has a 35% decrease in RGC numbers and a 39% decrease in amacrine cell numbers. The reduction in RGC numbers was not observed until after E16.5 correlating with increase in RGC apoptosis in the *Barhl2* mutant starting at E16.5. The *Barhl2* null retinas had a 95% reduction of

RGCs that lineage label with Barhl2 suggesting it is necessary for the development/survival of the RGCs it is expressed in (Mo, Li, Yang, & Xiang, 2004) (Q. Ding et al., 2009).

Pbx2&4 (Pre-B cell leukemia homeobox family of the Three Amino Acid Loop Extension class) have been studied in Telost retinal formation, but not in mouse. Pbx2&4 expression is seen shortly after optic cup formation and **Pbx1&3b** is expressed in the retina shortly after. Pbx4 null Teleost display a smaller eye phenotype. A Pbx2/Pbx4 null embryo displays normal retinal lamination with axons exiting the retina normally, but the axons stop right before the optic tectum. This suggests that Pbx2&4 are required for at least the RGC axon targeting in the brain. Interestingly, the authors also saw a massive reduction of Atoh7 in the dorsal retina in the Pbx1/Pbx2 null Teleost suggesting that Atoh7 is downstream of Pbx1&2 or the pathfinding and patterning of the retina leads to loss of Atoh7 expression in this region (French et al., 2007). The role of Pbx1,2,3,&4 is unknown in mouse retinal development.

Vax1 (Ventral-anterior homeobox family) is expressed starting at E8 and at E9-E14 it is expressed in the optic disk, optic stalk, optic chiasm, suprachiasmatic area, and the hypothalamic cell cord (Hallonet et al., 1998). In the Vax1 null mouse the astrocytes of the optic nerve fail to associate with the RGC axons leaving them naked. The RGC axons in the knockout also fail to enter the hypothalamus. Vax1 null optic fissure fails to close (Bertuzzi, Hindges, Mui, O'Leary, & Lemke, 1999).

Vax2 is a family member of Vax1, but it is first expressed at E9.0 in an asymmetric fashion in only the ventral optic vesicle. 70% of Vax2 null mouse have an

incomplete closure of the optic fissure in optic cup development. This is due to the incomplete ventralization in the null retina and also leads to deficits in ventral RGC axon guidance. Specifically, there are no ipsilateral projections and the ventral RGCs terminate where the dorsal RGCs usually terminate in the Superior Colliculus. The targeting deficit can be explained due to reduction in the gradient of EphB2 and EfnB2 expression in RGCs in the Vax2 null retina (Barbieri et al., 2002)(Barbieri et al., 1999).

Tbx2,3,5,&12 (T-box) are expressed beginning at E9.5 in the optic vesicle and are expressed in nested gradients within the dorsal retina. Single knockout of Tbx5 does not have an obvious retina phenotype, suggesting overlapping roles of the family members (Chapman et al., 1996; Schulte & Bumsted-O'Brien, 2008; Sowden, Holt, Meins, Smith, & Bhattacharya, 2001). Interestingly, ectopic ventral overexpression of Tbx5 in the developing chick retina leads to a “dorsalization” of the EphB/ephrinB molecules, but only a minor retinotectal pathfinding deficit was seen in this case (Koshiba-Takeuchi et al., 2000).

1.3 Human Pathologies

Studies have shown that the human homolog of Atoh7, ATOH7, play a similar role in the developing human retina as mutations of this gene have been implicated in genetic retinal diseases. Several single nucleotide polymorphisms (SNPs) in the ATOH7 locus are implicated in susceptibility to glaucoma (Fan, Wang, Pasquale, Haines, & Wiggs, 2011; Ramdas et al., 2011) and smaller optic disc area, as well as the optic cup to optic disk ratio (CDR) (Khor et al., 2011; Macgregor et al., 2010). Glaucoma is the

second leading cause of blindness worldwide, projected to affect 79.6 million people worldwide by 2020 (Quigley & Broman, 2006). Glaucoma is defined by RGC injury or malfunction followed by RGC death. Sometimes it is associated with an increase in intraocular pressure (IOP), however this is not always the case (Quigley & Broman, 2006). A smaller optic disk area in addition to a smaller CDR can lead to an increase in inability to diagnose glaucoma. It can also indicate reduced numbers of retinal ganglion cells, however this relationship is debated (Hoffmann, Zangwill, Crowston, & Weinreb, 2007)

Mutations in *ATOH7* have been associated with optic nerve hypoplasia (ONH) (reduction in size of the optic nerves) (Khan et al., 2012; Macgregor et al., 2010), optic nerve aplasia (ONA) (absence of optic nerves), and autosomal recessive persistent hyperplasia of the primary vitreous (arPHPV) (persistence of developmental vasculature in the retina), all of which lead to childhood visual impairment or blindness (Prasov, Masud, Khaliq, Mehdi, Abid, et al., 2012a). Severe ONH and ONA have been seen in humans with mutations in *OTX2*, *SOX2*, *PAX6*, *HESX1*, and *ATOH7*, however these genes do not explain all cases of ONH or ONA (Azuma et al., 2003; Dattani et al., 1998; Kelberman & Dattani, 2007; McCabe, Alatzoglou, & Dattani, 2011; Ragge et al., 2005). arPHPV occurs when the fetal hyaloid vasculature fails to regress and the retinal vasculature does not form, occurring in some human patients with *Atoh7* mutations and this pathology is also present in mouse *Atoh7* mutants (Edwards et al., 2012; Prasov, Masud, Khaliq, Mehdi, Abid, et al., 2012a).

1.4 Development of retinal vasculature

There are two main vascular networks in the retina, the choroid and the retinal vasculature. The choroid is directly below the retinal pigment epithelium (RPE), and supports the photoreceptors. The retinal vasculature is mainly superficial to the retina and provides support for the rest of the retina cells. The retinal vasculature is a beautiful network with three plexi; superficial (NFL), intermediate (IPL), and deep (OPL). However, in mice, this retinal vasculature network only develops after birth and can take up to three weeks to fully develop. To provide support to the lens and retina during embryonic retinal development, and while the retinal vasculature forms postnatally, there is the hyaloid vascular network. This Hyaloid vasculature forms at E10.5 and regresses after birth. The regression is substantial by P8 and is majorly regressed by P16, but traces can be found up until P30 when the retinal vasculature is fully formed (Dorrell, Aguilar, & Friedlander, 2002; Edwards et al., 2011). The mechanism of regression of the hyaloid vasculature is not fully known, but the timing of regression is refined by the retinal clock and Opn4/Opn5 mediated light activity in the retina. In the absence of Opn4, or when dark reared from E16-E17, the hyaloid vasculature regresses a few days later than normal (Rao et al., 2013). In the absence of Opn5 the hyaloid vasculature regresses a few days earlier (Nguyen et al., 2019). If the hyaloid vasculature partly or fully fails to regress there, it can lead to visual deficits later in life and it can prevent the retinal vasculature from properly forming. In mice there are multiple models of persistent hyaloid vasculature, including mutations in *Lrp5*, *Arf*, *Fzd4*, *Ang2*, *Bmp4*, and of interest to this study, *Atoh7* (Edwards et al., 2012; Prasov, Masud, Khaliq, Mehdi, Abid, et al., 2012a;

Saint-Geniez & D'amore, 2004). In the *Atoh7* mutant mice the hyaloid vasculature fails to regress and the retinal vasculature fails to form. The persistent hyaloid vasculature in these mice improperly dove into the retina to provide support that should have been provided by the retinal vasculature. These data lead Edwards et al to propose that RGCs are critical for this hyaloid vasculature regression and ILM development (Edwards et al., 2012; Yoshikawa et al., 2016). In *Brn3b* mutant mice, which experience early RGC loss, the superficial retinal vasculature also fails to form (Sapieha et al., 2008).

1.5 Retinal Transcription Factor Family Equivalence in the Development of RGCs

Several elegant genetic studies have addressed the mechanism by which *Atoh7* regulates RGC specification. In mouse, when *Neurod1*, a close homolog of *Atoh7*, was expressed from the *Atoh7* locus it rescued only 30% of wildtype RGC numbers and their axons were able to form an optic nerve with a size consistent with the lower number of RGCs (Mao, Wang, Pan, & Klein, 2008a). When *NeuroD1* and *Atoh7* were both mutated at the same time fewer RGCs were seen compared to the *Atoh7* mutant (Kiyama et al., 2011). In addition, ectopic *Atoh7* expression from the *Neurod1* locus causes an 30% increase over wildtype RGC numbers, and in *Atoh7* null animals, this ectopic expression rescued only 28% of RGCs that properly innervated retinorecipient areas in the brain (Mao et al., 2013). However, this was not observed when either of two other close homologues of *Atoh7* -- *Ascl1* or *Neurod4* -- were expressed from the *Atoh7* locus (Hufnagel et al., 2013; Mao, Wang, Pan, & Klein, 2008a). Selective rescue of *Atoh7*

expression during late retinal development in zebrafish, rescued the later born RGCs, but these RGCs were unable to project to the optic tecta. However, early born, *Atoh7* expressing, RGCs were sufficient to allow the later born RGCs to properly project to the optic tecta (Pittman, Law, & Chien, 2008). Similar results in mice were observed when *Atoh7* was expressed from the *Crx* locus, which is first expressed at E12.5 in precursor cells, the optic nerve was only weakly rescued and the number of RGCs present were only 12% of wildtype (Prasov & Glaser, 2012b). Remarkably, a full rescue of the *Atoh7* null was observed when only two transcription factors known to be required for RGC survival and development, the POU domain, class 4, transcription factor 2 (*Pou4f2*; also known as *Brn3b*) and Insulin gene enhancer 1, *Islet 1* (*Isl1*), were ectopically expressed from the endogenous *Atoh7* locus (Gan et al., 1999; L. Pan, Deng, Xie, & Gan, 2008; Wu et al., 2015). These studies show that *Pou4f2* and *Isl1* act downstream of *Atoh7*, and the regulation of their temporal expression by *Atoh7* is sufficient to restore wild-type-like RGCs.

1.6 Not all RGCs are of the *Atoh7* Lineage

A complication for the necessity of *Atoh7* in RGC specification, however, arises from an observation that only 55% of RGCs in adults are derived from the *Atoh7* lineage (Brzezinski et al., 2012; L. Feng et al., 2010; Poggi et al., 2005). Not only are only 55% of RGCs of the *Atoh7* lineage, but in the *Atoh7*^{Cre} mouse line only 11% of all *Atoh7* expressing cells become RGCs and that *Atoh7* is expressed in 2.9% of all retinal cell types, including some portion of every major cell type in the retina, specifically; 31% of

cones, 29% of amacrine cells, and <0.1% of Müller glia. One explanation for this finding is that the Atoh7^{Cre} mouse line might not reflect endogenous Atoh7 expression, due to leaky Cre activity (Brzezinski et al., 2012). However, the non-RGC cell labeling is consistent across animals and within the same retina, indicating this is unlikely to be “leaky” (Brzezinski et al., 2012; Prasov, 2012). This finding was shocking and quantified previously published reports in an independently made mouse model that showed Atoh7 lineage cells in all major cell types in the retina (L. Feng et al., 2010). These studies went against the current model in the field that suggests that Atoh7 is the master transcriptional regulator of RGC development. If that was the case, then all RGCs should express Atoh7 as they transition from RPCs to RGCs, and the expression of Atoh7 should be instructive of that transition. Also, Atoh7 should be only expressed in RGCs and not in other cell types. The non-RGC-lineage expression of Atoh7 could be explained as asymmetric division of RPCs to RGC and an RPC where the cre-recombinase protein diffuses throughout the dividing cell and thus labels all of its daughter cells. However, the under labeling of RGCs by multiple different Atoh7-driven cre recombinase lineage analysis studies, was never fully accepted. Excuses have been made as to why a certain cre-recombinase line was ineffective, for example a neomycin cassette was left in the locus and that it was a BAC transgenic without the entire regulatory regions. We have seen similar Atoh7 lineage labeling in our hands using different reporters, but the same Atoh7-cre mouse line. The explanation that was proposed by the is that there is a significant population, up to 45% of RGCs, that does not use Atoh7 in its specification. Our work provides substantial evidence that these prior lineage labeling studies are correct. Implicit

in this observation is that 45% of RGCs develop from non-Atoh7-positive precursors, but they are incapable of surviving in the absence of Atoh7, as the Atoh7 mutant lack 95% of RGCs.

1.7 Cell Death during Retinal Development

Cell death is an important part of retinal development, with apoptotic cell death observed in approximately 60-70% of RGCs during normal development (Farah & Easter, 2005; Mosinger Ogilvie, Deckwerth, Knudson, & Korsmeyer, 1998; Strom & Williams, 1998). There are at least three windows of apoptosis that occur during RGC development. The first of these is an early window that lasts from the onset of RGC generation until E13.5, and results in part from intra-retinal signaling of BDNF (Frade, Bovolenta, MartinezMorales, Arribas, & RodriguezTebar, 1997; Péquignot et al., 2003; Rodríguez-Gallardo, Lineros-Domínguez, Francisco-Morcillo, & Martín-Partido, 2005)(reviewed (Valenciano, Boya, & la Rosa, 2009)). The second window of programmed cell death, seen from birth until P12, is likely driven mainly by target derived neurotrophic factors (Linden & PINTO, 1985; Péquignot et al., 2003; Pollock et al., 2003; Strom & Williams, 1998; Young, 1984). The third window peaks around eye opening, lasting from P13 to P21, and is driven by refinement of intra-retinal connections (Péquignot et al., 2003; M. A. Williams, Piñon, Linden, & PINTO, 1990).

Apoptosis in all three of these periods is Bax(BCL2 Associated X, Apoptosis Regulator)-mediated, as in its absence there is 226% increase in RGC numbers (Mosinger Ogilvie et al., 1998; Péquignot et al., 2003). Consistent with this requirement for Bax,

loss of function of the programmed cell death 1 ligand 1 and ligand 2 (PD-L1/L2) lead to increased numbers of RGCs, although to a much lesser extent than Bax mutants (Braunger et al., 2013; Harada et al., 2006; Pollock et al., 2003; Sham et al., 2012). Surprisingly little is known about how the regulation of these different phases of retinal apoptosis is occurring, with most research focusing only on the P0-P12 phase. Targeted mutants of major neurotrophic receptors such as TrkA, TrkB, BDNF, p75, and TGFbeta all have no effects on adult RGC numbers (Harada et al., 2006; Pollock et al., 2003). The only exception is retinal-specific loss of function of Smad7, a downstream transcription factor that inhibits TGFbeta signaling, which leads to a modest increase of RGCs (17%), compared to Bax mutations. Conversely, TGF- β type II receptor knockouts led to a significant decrease in adult RGC (40%) number (Braunger et al., 2013). To further complicate the story, the developmental overproduction of RGCs is partially dependent on Atoh7 expression levels, as shown in Atoh7^{+/-} mouse, which at birth, has 30% fewer RGCs than wildtype littermates. This lower number of RGCs is corrected after the 2nd and 3rd phases of apoptosis (Prasov, Nagy, Rudolph, & Glaser, 2012b). Even though the earliest RGCs are born at E10.5, starting at E13.5 there is an increase in apoptotic cells in the non-Atoh7 dependent lineage in Atoh7 mutant mice. There is also an increase across retinal development in Atoh7-lineage cells across embryonic retinal development, and an increase in non-Atoh7-lineage cells in the GCL at E16.5 and E17.5 (L. Feng et al., 2010; Prasov & Glaser, 2012b). Interestingly, in zebrafish, there was no signs of apoptosis in the absence of Atoh7 (Kay et al., 2001). These data indicate that Atoh7 may play an underappreciated role in regulating apoptosis at early stages in retinal development.

In Zebrafish mutation of Atoh7 (lakritz), no apoptosis was seen by TUNEL staining (Kay et al., 2001). The differences between mouse and zebrafish could be due to the absence of the Atoh7-dependent survival signal leading to very fast death of developing RGCs, or cross-differentiation since the zebrafish retina is much more plastic. If the cell death is very fast the TUNEL staining might not be sensitive enough to see the apoptosis and the more sensitive “triple death stain” might resolve apoptosis on this timescale (S.-K. Chen et al., 2013). It is also possible that Atoh7 acts differently in zebrafish, who are constantly regenerating their retina throughout their life compared to mice. In the original mouse studies of Atoh7, the increase in apoptosis, now appreciated (L. Feng et al., 2010), was not seen (N. L. Brown et al., 2001), so it could have been missed, or an incorrect timepoint might have been studied, as they only looked at 30 or 48 hpf (Kay et al., 2001).

1.8 Extrinsic Factors in RGC Development

Gdf11, Vegf, Shh, Fgf, and Notch are all the known extrinsic signaling molecules involved in RPC division, RPC exit from cell cycle, and expression of Atoh7. Gdf11 (Growth differentiation factor 11)(TGF- β /BMP superfamily), expressed in neuroblast later (NBL) and GCL, negatively regulates the number of RGCs and is antagonized by Fst (Follistatin-like 3). Fst forms inactive complexes with Gdf11, is expressed in the GCL, and is a positive regulator of RGC development. Gdf11 signaling has a larger effect during the second half of RGC development, as RGC density increases. The increase of RGCs seen in the absence of Gdf11 is at the expense of bipolar and amacrine cells (Kim

et al., 2005). Vegf, secreted by RGCs, acts on RPCs, promoting their proliferation and suppressing RGC development, through the Vegfr2/Flk1 receptor and Hes1 (Hashimoto, Zhang, Chen, & Yang, 2006; Nishiguchi, Nakamura, Kaneko, Kachi, & Terasaki, 2007). Notch3-Rbpj-Hes1 signaling negatively regulates RGC genesis and positively regulates RPC proliferation, however Rbpj and Hes1 can both be activated independently of Notch signaling. Notch1 has also been seen to promote RPC proliferation while inhibiting RPC cell cycle exit, and RGC genesis (Hashimoto et al., 2006; Miesfeld et al., 2018; A. N. Riesenberger, Liu, Kopan, & Brown, 2009b; Yaron, Farhy, Marquardt, Applebury, & Ashery-Padan, 2006). Shh is expressed by RGCs and has been shown to negatively regulate RGC genesis and Atoh7 expression at the point of terminal differentiation as well as positively regulate Hes1, and RPC cell cycle. Shh signals to the RPCs through Gli1 in a short-range fashion. Shh assists, but is not necessary, for the maintenance of the neurogenic wave front, driven by Neurog2, for RGC genesis (Hufnagel et al., 2010; Sakagami, Gan, & Yang, 2009; Y. P. Wang, Dakubo, Thurig, Mazerolle, & Wallace, 2005b; X. M. Zhang & Yang, 2001). Besides target derived factors in the retino-recipient targets, there are no extrinsic factors are known that regulate RGC survival in the retina.

1.9 Diversity of RGCs

Up until recently there was thought to be 25-32 different types of RGCs many of which transmit different types of information from the retina to the almost 46 retino-recipient areas in the brain (Baden et al., 2016; Masland, 2001; Morin & Studholme, 2014; Sanes & Masland, 2015; Wernet, Huberman, & Desplan, 2014). The classification of an RGC type was done by a combination of morphological, electrophysiological, genetic, and retinal distribution analysis. However, the genetic analysis done up until recently has been low throughput, especially at higher or single cell resolution. Using scRNA-seq of P5 mouse retina, 40 types of RGCs were genetically defined. These data came from the analysis of the transcriptome of 6,225 RGCs. And since this analysis was done at P5, before eye opening, it is possible for the 40 types of RGCs to further diversify into subtypes or more types after eye opening and the completion of eye development. The 40 different types of RGCs were able to be distinguished by a combination of mostly 2 to sometimes 3 genes (Rheaume et al., 2018). The differential regulation of transcription factors that combine to create the diversity in RGC type (dendritic arbor size, electrophysiological properties, brain targets, soma size, etc.) are mostly unknown and a current topic of intense research, a few of the understood mechanisms are mentioned above and the other known factors will not be covered in this thesis (Wernet et al., 2014). However, the current dogma that all 40 of these very diverse and distinct types of RGCs arise from *Atoh7* just does not follow common sense. It makes more sense that to generate such a diverse pool of RGCs multiple different and parallel pathways would

be in place, our work, seen in the following chapter, along with others beautiful work vividly suggest this.

1.10 Summary

The necessity but not sufficiency of Atoh7 in the development of RGCs, its expression in only 55% of RGCs, and the increase in RGC cell death seen in the absence of Atoh7, brought us to directly investigate whether Atoh7 indeed acts solely as an RGC specification factor. To differentiate functions of Atoh7 in RGC specification and in regulation of RGC survival, we re-examined the Atoh7 null mouse line on a background that prevents RGC death by knocking out the proapoptotic gene, Bax. If Atoh7 were only responsible for RGC specification and not RGC survival, inhibiting cell death in Atoh7 knockout animals should cause no differences in RGC number relative to animals lacking Atoh7 alone. However, If Atoh7 plays a role in the developmental survival of all RGCs and not their specification, then in the absence of Atoh7 and Bax, RGCs would develop normally. We observed that substantial numbers of retinal progenitor cells differentiate into normal RGCs in the absence of Atoh7 and Bax. These RGCs failed to project to the brain but were able to form functional retinal circuitry. Furthermore, these RGCs showed nearly identical expression of RGC transcripts, with some clear differences that could implicate factors in specification and or survival of RGCs. Our data show conclusively that there are, at least, two populations of RGCs, those that require Atoh7 for specification and those that do not, however nearly all RGCs require Atoh7 for developmental survival in a cell non-autonomous fashion.

Chapter 2 – Atoh7-independent specification of retinal ganglion cell identity

This chapter is based on a manuscript currently in submission:

2.1 Abstract

Retinal ganglion cells (RGCs) relay visual information from the eye to the brain. RGCs are the first cell type generated during retinal neurogenesis. Loss of function of the transcription factor *Atoh7*, expressed in multipotent early neurogenic retinal progenitor cells, leads to a selective and essentially complete loss of RGCs. Therefore, *Atoh7* is considered essential for conferring competence on progenitors to generate RGCs. DNA binding sites analysis of *Atoh7* using the Cut&Run method demonstrates that *Atoh7* directly targets genes controlling RGC specification. Despite the important function of *Atoh7* in RGC specification, when apoptosis is inhibited in *Atoh7*-deficient mice by loss of function of *Bax*, only a modest reduction in RGC number is observed. Single-cell RNA-Seq of *Atoh7*;*Bax*-deficient retinas shows that RGC differentiation is delayed, but that the gene expression profile of RGC precursors is grossly normal. *Atoh7*;*Bax*-deficient RGCs eventually mature, fire action potentials, and incorporate into retinal circuitry, but exhibit severe axonal guidance defects. This study reveals an essential role for *Atoh7* in RGC survival and demonstrates *Atoh7*-independent mechanisms for RGC specification.

2.2 Introduction

The retina has six major classes of neurons that develop from a common progenitor cell pool during overlapping temporal intervals. Retinal ganglion cells (RGCs), the only projection neurons from the retina to the brain, are the first retinal cell type to be generated. RGC development in zebrafish, mice, and humans has been shown to require the basic helix-loop-helix transcription factor atonal homolog 7 - *Atoh7* (*Math5*) (Brown et al., 2001; Ghiasvand et al., 2011; Jarman et al., 1994; Khan et al., 2011; Khor et al., 2011; Macgregor et al., 2010; Prasov et al., 2012; Wang et al., 2001). *Atoh7* is conserved across all vertebrate species, and distantly related to *atonal*, which specifies the earliest-born neurons in *Drosophila* retina (Brown et al., 2001; Jarman et al., 1994; Kanekar et al., 1997; Prasov et al., 2012). *Atoh7*-deficient mice and zebrafish lack upwards of 95% of RGCs (Brown et al., 2001; Brzezinski et al., 2012; Kay et al., 2001; Wang et al., 2001) and likewise lack any visible optic nerve or functional connections from the retina to the brain (Brzezinski et al., 2005; Wee et al., 2002). Human mutations in *ATOH7* or its cis-regulatory regions have been associated with optic nerve agenesis or hypoplasia (Khan et al., 2012; Macgregor et al., 2010) and increased susceptibility to glaucoma (Fan et al., 2011; Ramdas et al., 2011). *Atoh7*-deficiency also disrupts the development of retinal vasculature in both mice and humans, likely as an indirect result of the loss of RGCs (Edwards et al., 2012).

In mice, *Atoh7* is expressed in neurogenic retinal progenitor cells (RPCs) between E12 and P0, corresponding to the interval in which RGCs are generated (Brown et al., 1998; Clark et al., 2019; Feng et al., 2010; Pacal and Bremner, 2014; Prasov and Glaser,

2012; Rapaport et al., 2004; Sidman, 1960; Wang et al., 2001; Young, 1985). Upon cell fate specification, *Atoh7* expression is rapidly down-regulated in mouse RGC precursors (Clark et al., 2019; Miesfeld et al., 2018a) although expression persists in immature human RGCs (Aparicio et al., 2017; Lu et al., 2020). Genetic fate mapping indicates that *Atoh7*-expressing RPCs also give rise to other early-born retinal cells, including cone photoreceptors, horizontal and amacrine cells, and that generation of these cell types is increased in *Atoh7*-deficient mice (Brown et al., 2001; Brzezinski et al., 2005; Hufnagel et al., 2013; Wang et al., 2001). Ectopic expression of *Atoh7* alone, however, typically is not sufficient to drive RGC specification (Gan et al., 1999; Hufnagel et al., 2013; Mao et al., 2013, 2008; Ohnuma et al., 2002; Pan et al., 2008; Pittman et al., 2008; Prasov and Glaser, 2012; Wu et al., 2015), although misexpression of *Atoh7* in *Crx*-expressing photoreceptor precursors was sufficient to rescue the development of a limited number of RGCs (Prasov and Glaser, 2012).

These findings have suggested that *Atoh7* acts in neurogenic RPCs to confer competence to generate RGCs (Brzezinski et al., 2012; Mu et al., 2005; Yang et al., 2003) potentially in combination with as yet unidentified factors. Recent experiments have shown that when *Pou4f2* and *Isl1* are expressed under the control of the endogenous *Atoh7* promoter, these transcription factors are sufficient to fully rescue the defects in RGC development seen in *Atoh7* mutants (Gan et al., 1999; Pan et al., 2008; Wu et al., 2015). This implies that *Atoh7* may act permissively to enable the expression of these two factors in early-stage RPCs.

Other data, however, suggest that a large number of RGCs are specified independent of *Atoh7*. Previous studies indicate that immature RGCs are present in *Atoh7*-deficient mice in embryonic retina, although at reduced numbers relative to controls (Brown et al., 2001; Brzezinski et al., 2012). Genetic fate-mapping studies further raise questions about the necessity of *Atoh7* for all RGC specification. Analysis of *Atoh7-Cre* knock-in mice reveals that only 55% of all RGCs are generated from *Atoh7*-expressing RPCs (Brzezinski et al., 2012; Feng et al., 2010; Poggi et al., 2005). Although this outcome may reflect inefficient activation of Cre-dependent reporter constructs, it may also imply that a subset of RGCs is specified through an *Atoh7*-independent mechanism that requires trophic support from *Atoh7*-expressing RPCs or *Atoh7*-derived RGCs.

To distinguish the role of *Atoh7* in controlling RGC specification and survival, we prevented RGC death in *Atoh7*-deficient mice by simultaneously inactivating the proapoptotic gene *Bax* (Chen et al., 2013; Knudson et al., 1995). The idea being if RGCs can be specified in the absence of *Atoh7* but require it for trophic support, we should reveal RGCs that are specified in an *Atoh7*-independent manner when cell death is prevented. Strikingly, we observed only a $25.2 \pm 0.9\%$ reduction in adult RGC numbers in *Atoh7*^{-/-};*Bax*^{-/-} retinas relative to *Bax*^{-/-} controls, implicating an unrecognized *Atoh7*-independent specification pathway for RGCs. While mutant RGCs showed severe defects in the formation of axonal projections and retinal vasculature, we found that the *Atoh7*-independent RGCs expressed both *Pou4f2* and *Isl1*, the two transcription factors that are sufficient to fully compensate for *Atoh7* function. These RGCs also fired action

potentials in response to light and formed functional synapses with upstream retinal neurons. Single-cell RNA-Sequencing (scRNA-Seq) analysis of *Atoh7*;*Bax*-deficient retinas shows that *Atoh7*-deficient RGC differentiation is delayed relative to wildtype, implicating *Atoh7* as responsible for generating the early born pioneering RGCs. Our results imply a new pathway for specifying RGCs that is independent of *Atoh7*.

2.3 Results

2.3.1 *Atoh7* promotes RGC survival, but RGC specification is largely *Atoh7*-independent

In the absence of *Atoh7*, there is an increase in apoptosis of both *Atoh7*-derived cells across embryonic retinal development and non-*Atoh7*-derived cells in the GCL at E16.5 and E17.5 (Feng et al., 2010; Prasov and Glaser, 2012). These data suggest that *Atoh7* may promote RGC survival in both a cell-autonomous and cell non-autonomous manner. To better understand the role *Atoh7* plays in RGC development, independent of its role in RGC survival, we disrupted both *Atoh7* and the proapoptotic *Bax* gene, in order to inhibit apoptosis in the retina.

We used *Atoh7*^{Cre/Cre} mice, in which the *Atoh7* coding sequence is replaced with Cre recombinase via targeted recombination, generating a null allele, to analyze *Atoh7* function (Yang et al., 2003). We first examined the expression of RBPMS and *Isl1*, both of which are broadly expressed in RGCs, in *Atoh7*^{Cre/Cre};*Bax*^{-/-} mice (Figure 1A-C) (hereafter referred to as *Atoh7*^{-/-};*Bax*^{-/-} mice). *Isl1*, a LIM family homeodomain transcription factor, is necessary for RGC development and maintenance in adulthood

(Mu et al., 2008; Pan et al., 2008), and is expressed in mature RGCs, bipolar, and amacrine cells. Using anti-Rbpms to selectively label all RGCs, we observed an $159\pm 7\%$ (Figure 1A,B) increase in RGC number in *Bax*^{-/-} retinas, in line with previous results indicating that RGCs undergo extensive levels of apoptosis during development. However, we observe only a $25.2\pm 0.9\%$ reduction in RGCs in *Atoh7*^{-/-};*Bax*^{-/-} relative to *Bax*^{-/-} retinas. This contrasts with the $99.54\pm 0.12\%$ reduction in RGCs in the *Atoh7*^{-/-} compared to controls (Figure 1A,B). Similar results were observed for anti-Is11 cells in the GCL (Figure 1A,C).

Specific RGC markers, Brn3a (Pou4f1) and Brn3b (Pou4f2), were used to quantify RGCs. For wildtype and *Bax*^{-/-} lines, Brn3a and Brn3b numbers were similar to published reports (Figure 1D-F) (Prasov and Glaser, 2012; Rodriguez et al., 2014; Wang et al., 2001; Xiang et al., 1995). In the *Atoh7*^{-/-} line a $99.8\pm 0.2\%$ reduction in Brn3a RGC density was observed. However, in *Atoh7*^{-/-};*Bax*^{-/-} mice, the Brn3a RGCs were substantially rescued in the *Atoh7*^{-/-} background and remained into adulthood. $74.7\pm 0.9\%$ of Brn3a RGCs are rescued in *Atoh7*^{-/-};*Bax*^{-/-} mice relative to *Bax*^{-/-} levels in adult, and RGCs display normal distribution across the entire retina (Figure 1D,E, Supplemental Figure 1A,A'). Interestingly, Brn3b RGCs were also rescued in *Atoh7*^{-/-};*Bax*^{-/-} relative to *Bax*^{-/-} retinas, but to a much lesser extent than the Brn3a ($28.8\pm 5.9\%$; Figure 1D,F, Supplemental Figure 1B,B'). Expression of *Is11*, *Brn3b*, and, to a lesser extent *Brn3a* have previously reported to require *Atoh7* (Mu et al., 2008, 2004, 2005; Pan et al., 2008; Rodriguez et al., 2014; Wu et al., 2015). However, our data demonstrates that the

expression of *Isl1*, *Brn3a*, and *Brn3b* in RGCs can occur independent of *Atoh7* (Figure 1).

To investigate the extent to which rescued RGCs resembled wildtype neurons, we examined the expression of markers of major classes of mature RGCs. We investigated the prevalence of intrinsically photosensitive RGCs (ipRGCs) within *Atoh7*^{-/-};*Bax*^{-/-} retinas. During the development of ipRGCs, a majority of cells express *Brn3b*, although in some cases only transiently (Chen and Hattar, 2012). To determine the percentage of rescued ipRGCs in *Atoh7*^{-/-};*Bax*^{-/-} mice, we used a melanopsin antibody that predominantly labels the high melanopsin-expressing M1 and M2 ipRGC populations. We observe that 34.1% of ipRGCs are rescued in *Atoh7*^{-/-};*Bax*^{-/-} mice relative to *Bax*^{-/-}, proportions similar to the fraction of *Brn3b*-positive RGCs in wildtype (Figure 1D,F, Supplemental Figure 1C-F). This indicates that rescued *Brn3b*-positive ipRGCs can differentiate in the absence of *Atoh7*.

To eliminate the possibility that global loss of function of *Bax* caused a non-specific rescue of RGC development, we tested the effects of retina-specific conditional mutants of *Bax*, using *Chx10-Cre*;*Atoh7*^{Cre/Cre};*Bax*^{fl/fl} (Figure 1G,H). In this model, *Bax* is selectively disrupted in RPCs beginning at E10-10.5 (Rowan and Cepko, 2004). Removal of *Bax* from all RPCs shows RGC development to the same extent as in *Atoh7*^{Cre/Cre};*Bax*^{-/-} (Figure 1G, H). This indicates that the rescue of RGCs is specific to the retina.

We then reasoned if cell death has to be rescued specifically in *Atoh7*-independent RGCs, then *Atoh7*^{Cre/Cre};*Bax*^{fl/fl} mice should fail to rescue the deficits of the lack of *Atoh7*. In fact, we observed that *Atoh7*^{Cre/Cre};*Bax*^{fl/fl} mice did not show any

detectable rescue of RGC development (Figure 1G,H), suggesting that cell death rescue in non-*Atoh7* cells is necessary for RGCs to differentiate and form connections with retinal neurons.

In both wildtype and *Atoh7*^{-/-};*Bax*^{-/-} animals, 34±11% and 34±26% of RGCs, respectively, are derived from *Atoh7*-expressing cells, a finding which independently confirms similar lineage tracings in previous studies (Supplemental Figure 2A-C) (Brzezinski et al., 2012; Feng et al., 2010). This indicates that while RGCs that are normally derived from *Atoh7*-expressing neurogenic RPCs are reduced in the absence of *Atoh7*, *Atoh7* is not required for their specification. Furthermore, RGCs that are derived from non-*Atoh7*-expressing RPCs require *Atoh7* for survival through a non-cell autonomous mechanism.

2.3.2 RGCs specified in the absence of *Atoh7* generate light-driven photic responses transduced from the outer retina

As we determined that loss of *Bax* in the *Atoh7*^{-/-} background rescues a large percentage of RGC specification, we next sought to investigate the degree to which RGCs differentiated in the absence of *Atoh7*. One hallmark of RGC differentiation is the formation of presynaptic contacts and the generation of light-induced action potentials. We used multi-electrode array (MEA) recordings to test the light responsiveness of the RGCs within the various mutant models. Spatiotemporal noise stimuli were used to activate the retina with a mean excitation of 398 nm ($I_{\text{mean}} \approx 5 \times 10^3$ photons/cm²/s), a wavelength that predominantly activates S-cones (Wang et al., 2011), and does not

activate Opn4-expressing ipRGCs (Berson et al., 2002; Do, 2019; Do and Yau, 2010; Hattar et al., 2002). We observed an identical stimulus-response profile in wildtype and *Bax*^{-/-} RGCs (Figure 2A): an expected result given that *Bax*^{-/-} mice display normal visual responses within the Morris water maze test (Chen et al., 2013). The population of RGCs included cells with similar light-evoked responses as ON sustained, ON transient, ON/OFF transient, OFF transient, or OFF sustained RGCs (Figure 2A, Supplemental Figure 3). The spatial receptive fields of the *Atoh7*^{-/-};*Bax*^{-/-} RGCs were slightly smaller than normal (*Atoh7*^{-/-};*Bax*^{-/-} average 191±37.1 μm [n=56 from 8 mice], control average 212±42.3 μm [n=92 from 5 mice] and *Bax*^{-/-} average 223±42.4 μm [n=96 from 4 mice]) (Figure 2B) and the kinetics of the light-driven responses in the *Atoh7*^{-/-};*Bax*^{-/-} retinas slightly slower than those of control and *Bax*^{-/-} cells (Figure 2C).

The linear analysis used for the MEA data can only reveal an averaged spike triggered averaging (STA), which could be a compression of multiple receptive fields. Thus those having multiple receptive fields such as ON-OFF cells could potentially be hidden with this method and require more sophisticated analysis strategy (Shi et al., 2019). However, diversity in peristimulus time histogram (PSTH) profiles is clearly observed, suggesting that different cell types coexist in *Atoh7*^{-/-};*Bax*^{-/-} mice. We chose not to perform more complex analysis such as classifying each cell into known cell types due to the relatively small sample size. These will be intriguing questions to address when larger amounts of data are made accessible. The near-normal properties of the *Atoh7*^{-/-};*Bax*^{-/-} RGCs show that RGCs present in the *Atoh7*^{-/-};*Bax*^{-/-} are wired properly to the outer retina, specifically the S-cones, and receive normal circuit input.

2.3.4 RGC axon guidance is *Atoh7*-dependent

While RGCs in *Atoh7*^{-/-};*Bax*^{-/-} animals appropriately respond to the detection of visual stimuli by the outer retina, the ability of these RGCs to form postsynaptic connections in the brain is compromised. We observed a substantially reduced pupillary light response (PLR) in *Atoh7*^{-/-};*Bax*^{-/-} animals compared to controls (Figure 3B,C). To determine the cause of behavioral deficits, we assessed the distribution of RGC axons. Immunostaining for Smi32 (non-phosphorylated Nfh) (Figure 3A,D, Supplemental Figure 4C), Nfh, and Nfm (Supplemental Figure 4A,B) was used to evaluate RGC axonal integrity, and showed normal architecture in wildtype and *Bax*^{-/-} mice. We were surprised to find that the <1% of RGCs that survive in the *Atoh7*^{-/-} showed severe guidance defects, in that they fasciculate, come in close proximity to where the optic disc should be, seem to overshoot the optic disc, and then continue to extend within the retina. The great majority of *Atoh7*^{-/-} RGC axons fail to correctly target the optic disc, with only a few axons exiting and forming a rudimentary optic nerve, leading to a severely reduced PLR (Figure 3B,C, Supplemental Figure 5A-C). The gross misguidance of axons was also observed in *Atoh7*^{-/-};*Bax*^{-/-} mice (Figure 3A,D). As in *Atoh7*^{-/-} mice, RGC axons in *Atoh7*^{-/-};*Bax*^{-/-} mice fasciculate, fail to correctly target the optic disk, and form tracts that extend around the retina, with only rudimentary optic nerves observed. This guidance defect did not result from the defective formation of the optic disc, as Pax2-positive glial cells that mark this structure are present in the *Atoh7*^{-/-};*Bax*^{-/-} at E12.5 (Supplemental Figure 6A,B). This demonstrates that the optic disk is present, but the axons are unable to find their way out of the retina in large numbers. These findings are reminiscent of previous reports in

zebrafish, in which morpholino-mediated disruption of *atoh7* expression in early-stage RPCs disrupted the correct targeting of axons of later-born, *atoh7*-positive RGCs to the optic tectum (Pittman et al., 2008).

Previous studies have observed a lack or massive reduction in physical or functional connection to the brain in *Atoh7*^{-/-} mice (Brown et al., 2001; Brzezinski et al., 2005; Triplett et al., 2011; Wee et al., 2002). Consistent with the failure of mutant RGCs to correctly target the optic nerve, we observe severe disruptions in behavioral responses to light in *Atoh7*^{-/-}; *Bax*^{-/-} mice that are essentially indistinguishable from those seen in *Atoh7*^{-/-} mice. *Atoh7*^{-/-}; *Bax*^{-/-} mice show no detectable optokinetic response (Supplemental Figure 7A), and show no visual cue-dependent reduction in escape time during successive trials of the Morris water maze (Supplemental Figure 7B). *Opn4:Tau-lacZ* knock-in mice, which visualize the axonal projections of M1 ipRGCs, show no detectable signal in the brain (Supplemental Figure 7C) (Hattar et al., 2002). Intraocular injection of fluorescently-labeled cholera toxin beta, which visualizes RGC axonal terminals (Bedont et al., 2014), likewise shows no brain labeling in both *Atoh7*^{-/-}; *Bax*^{-/-} and *Atoh7*^{-/-} mice (Supplemental Figure 7D). However, while the contralateral PLR is significantly reduced compared to wildtype in both the *Atoh7*^{-/-} and *Atoh7*^{-/-}; *Bax*^{-/-} mice, it is nonetheless detectable, indicating that a small number of RGC axons target the olivary pretectal nucleus in *Atoh7*^{-/-}; *Bax*^{-/-} mice, although we are unable to detect these using standard techniques (Figure 3B,C, Supplemental Figure 5 A-C).

2.3.4. Retinal vasculature development is disrupted in the absence of *Atoh7*

In both mice and humans, loss of *Atoh7* expression results in persistence of the hyaloid vasculature (Edwards et al., 2012; Ghiasvand et al., 2011; Kondo et al., 2016; Prasov et al., 2012). The persistence of the hyaloid vasculature in *Atoh7*^{-/-} retinas until P14 was previously observed. We likewise observe persistence of the hyaloid vasculature into adulthood in *Atoh7*^{-/-} retinas (Figure 3E), which is observed even in one year old mice (data not shown). Surprisingly, even with the rescue of a majority of Brn3a RGCs in *Atoh7*^{-/-}; *Bax*^{-/-} animals, the hyaloid vasculature still fails to regress (Figure 3E). Likewise, *Crx*>*Atoh7*; *Atoh7*^{-/-} mice, in which *Atoh7* is misexpressed in photoreceptor precursors, also fail to induce hyaloid regression (Figure 3E). This is in sharp contrast to the rescued vascular phenotype observed in *Atoh7*^{TA/TA}; *B&I-EE* mice, when *Brn3b* & *Isl1* are ectopically expressed from the endogenous *Atoh7* locus in a *Atoh7*-deficient mouse using the tet-off system (Wu et al., 2015)(Figure 3E), and implies that *Brn3b* and *Isl1* may activate expression of secreted factors that drive vascular regression in a narrow time window during development.

2.3.5 ScRNA-seq analysis of RGCs generated in the absence of *Atoh7*

In order to examine potential differences in RGC development within *Atoh7*^{-/-} and *Atoh7*^{-/-}; *Bax*^{-/-} compared to wildtype and *Bax*^{-/-} control animals, we next performed single-cell RNA-sequencing (scRNA-Seq) on *Bax*^{-/-}, *Atoh7*^{-/-}, and *Atoh7*^{-/-}; *Bax*^{-/-} retinas to more comprehensively profile changes in cell type specification and global transcriptional

differences across the genotypes. We profiled 67,050 E14.5 retinal cells from *Bax*^{-/-}, *Atoh7*^{-/-}, and *Atoh7*^{-/-};*Bax*^{-/-} mice, and aggregated the datasets with 26,078 age-matched wildtype retinal cells from previous studies (Clark et al., 2019) (Figure 4A,B, Supplemental Figure 8). Consistent with the previous single-cell studies of E14 mouse retinal development (Clark et al., 2019; Giudice et al., 2019), we observed a continuous manifold of cells, from primary RPCs to neurogenic RPCs, leading to three separate differentiation trajectories that give rise to RGCs, cones, and amacrine/horizontal cells, respectively (Figure 4A-B; Supplemental Figure 9A). Analysis of the cell type proportions across the genotypes revealed a depletion of RGCs in both *Atoh7* mutant samples (*Atoh7*^{-/-} and *Atoh7*^{-/-};*Bax*^{-/-}) compared to both wildtype and *Bax*^{-/-} controls (Figure 4C-D, Supplemental Figure 8E-F). This reduction in the number of RGCs included a compensatory increase in cone photoreceptors and neurogenic RPCs, consistent with previous findings (Figure 4C-D, Supplemental Figure 8E-F) (Brown et al., 2001; Brzezinski et al., 2005; Hufnagel et al., 2010; Wang et al., 2001).

Using the scRNA-seq data, we next assessed the differential gene expression within neurogenic RPCs and RGCs across control -- WT and *Bax*^{-/-} -- and *Atoh7*-deficient -- *Atoh7*^{-/-} and *Atoh7*^{-/-};*Bax*^{-/-} -- samples. Using strict differential expression cutoffs (q-value < 1e-300), we identified 230 *Atoh7*-dependent differentially expressed transcripts within neurogenic RPCs and RGCs (Table 1). Genes enriched within control samples (Figure 4E) highlighted many known factors in the specification and differentiation of RGCs, including *Pou4f2* (*Brn3b*), *Isl1*, *Pou6f2* (*Rpf-1*), *Elavl4*, *Gap43*, and *Irx2* (Choy et al., 2010; Ekström and Johansson, 2003; Kruger et al., 1998; Zhou et al., 1996)

(Supplemental Figure 9B). Conversely, differentially expressed transcripts enriched in the *Atoh7* knockout samples (Figure 4E) were enriched for genes involved in the Notch-signaling pathway -- *Rbpj*, *Dll3*, *Notch1*, and *Hes6* -- and for transcripts enriched in neurogenic cells and photoreceptor precursors during retinal development -- *Btg2*, *Neurog2*, *Bhlhe22*, *Insm1*, *Neurod1*, *Mybl1*, *Sstr2*, *3110035E14Rik* (Clark et al., 2019; Supplemental Figure 9B).

Atoh7-deficient RGCs also show dramatically reduced expression of genes known to regulate axon guidance including *Isir2*, which has been found to control RGC axon fasciculation, as well as axon guidance at the optic chiasm (Panza et al., 2015). Of particular interest are the observed increases in *Rbpj* and *3110035E14Rik* expressions in *Atoh7*^{-/-} and *Atoh7*^{-/-};*Bax*^{-/-} samples. *Rbpj* is an upstream regulator of *Atoh7* expression (Miesfeld et al., 2018b), and *3110035E14Rik* (*Vxn*), which functions similarly to *Atoh7* by promoting retinal neurogenesis and early retinal cell fate specification (Moore et al., 2018). The increased expression of transcripts that show enriched expression in neurogenic cells and photoreceptor precursors is consistent with the increase in generation of cone photoreceptor precursors seen in *Atoh7*-deficient retinas (Fig. 4D) (Brown et al., 2001). Combined with a recovery in the specification of RGC numbers in adult *Atoh7*^{-/-};*Bax*^{-/-} animals, these data suggest that loss of *Atoh7* expression leads to an increase in expression of genes specific to neurogenic RPCs at the expense of RGC-enriched transcripts, results consistent with a developmental delay.

2.3.6 Pseudotemporal analyses identify changes in *Atoh7*-dependent gene expression during RGC specification.

In order to further assess the degree of an RGC-specific developmental delay, we performed pseudotemporal analyses using Scanpy (Wolf et al., 2018)(Figure 4F). We observed bias of the *Atoh7*-deficient cells within early pseudotime stages during RGC differentiation. Both wildtype and *Bax*^{-/-} control cells had a broader distribution of cells across pseudotime, results consistent with a failure of maturation or developmental delay of RGC specification in *Atoh7*-deficient RGCs (Figure 4G). Differential expression analysis assessing the changes in gene expression across the interaction of pseudotime and genotypes revealed significant genotypic differences across RGC development (Figure 4H).

In both *Atoh7*^{-/-} and *Atoh7*^{-/-};*Bax*^{-/-} samples, we observed a reduction of expression in many genes enriched within mature RGCs -- *Pou4f2*, *Gap43*, *Sncg*, and *Isl1*. We likewise observed reduced expression of a subset of genes in neurogenic RPCs, including *Gal*. Increased expression of other genes predominantly expressed in neurogenic RPCs -- including *Neurod1*, *Insm1*, *Neurod4*, *Hes6*, *Onecut1*, *Onecut2*, and *Sox4* -- is observed in both *Atoh7*-deficient neurogenic RPCs and RGCs compared to controls (Figure 4H). This implies that loss of function of *Atoh7* may delay the differentiation of RGCs from neurogenic RPCs. The temporal expression patterns of genes involved in RGC specification mimic those observed within additional E14 scRNA-seq datasets (Giudice et al., 2019), and analyses of transcriptomic changes

resulting from loss of *Atoh7* expression closely match those obtained from scRNA-Seq-based analysis of *Atoh7*^{-/-} retina conducted at E13.5 (Wu et al., 2020).

We next performed *in situ* hybridization to examine changes in global transcript expression within the developing retina. RNA transcript expression was detected at E14.5, at which point most RGCs are specified (Sidman, 1960; Young, 1985), and we observed decreased expression of *Pou4f2* (*Brn3b*), *Isl1* and *Gal*, in both *Atoh7*^{-/-} and *Atoh7*^{-/-};*Bax*^{-/-} mice, as determined by chromogenic *in situ* hybridization (Figure 4I). Immunostaining of E14 retinas confirms a reduction in the number of cells immunopositive for Brn3a (*Pou4f1*) and Brn3b (*Pou4f2*) (Figure 4J), as well as the pan-RGC markers RBPMS and *Isl1* (Figure 4K), in the developing ganglion cell layer of *Atoh7*-deficient retinas. At E12.5 we observed a marked decrease in both overall RGC density and RGC number (Supplemental Figure 3). Together these results suggest that loss of function of *Atoh7* delays RGC differentiation and leads to an accumulation of neurogenic RPCs.

To further identify patterns of temporal changes in gene expression across RGC genesis between *Atoh7* mutant and control retinas, we performed the non-negative matrix factorization technique scCoGAPS (Stein-O'Brien et al., 2019). Implementation of scCoGAPS parses the gene expression into groups ('patterns') based on gene expression profiles and without *a priori*, literature-based knowledge of gene interactions. Using 5235 highly variable genes across the 29,182 neurogenic RPCs and differentiating RGCs, we identified 31 patterns of gene expression (Supplemental Figure 10). These patterns correlated with both neurogenic RPCs Patterns 6, 25, 5, 24, 11, 13, 18, 7, 21, 1, and 4

and RGC Patterns 8, 27, 28, 9, 26, 20, 22, 17, 31 cell type annotations and highlighted temporal changes in gene expression as assessed through pseudotime analyses. Individual patterns - patterns 4, 5, and 29 - were highly correlated with neurogenic cell annotations and *Atoh7*^{-/-} and *Atoh7*^{-/-};*Bax*^{-/-} genotypes, consistent with a temporal delay in RGC specification, increased number of neurogenic cells, or failure of cell-type specification of neurogenic RPCs as a consequence of lost *Atoh7* expression. Genes driving pattern 5 include genes enriched in early-stage neurogenic RPCs, *Gadd45a* and *Sox11* (Clark et al., 2019).

Conversely, patterns highly correlated with RGC cell type annotations and pseudotime Patterns 9, 26, and 28 had a high correlation with control samples. The most highly weighted genes in Patterns 9 and 26 are *Gap43* and *Igfbp11*, respectively, which have been implicated in RGC axonal growth (Guo et al., 2018; Zhang et al., 2000). Pattern 28 highlights cells towards the end of the RGC trajectory and is largely driven by *Sncg*; a transcript enriched in most RGCs in the adult mouse retina (Soto et al., 2008). The association of neurogenic patterns with *Atoh7*^{-/-} mutant retinas versus those that highlight RGC differentiation and maturation patterns with control retinas further support a developmental delay in mutant RGCs. Analysis of pattern marker expression across the genotypes (Supplemental Figure 10) highlights both the temporal delay and global changes in gene expression across the *Atoh7*^{-/-} mutant retinas compared to controls.

Recent studies have comprehensively profiled RGC subtype diversity in the mouse retina (Rheume et al., 2018; Tran et al., 2019). However, these studies did not characterize either the birthdates of individual RGC subtypes, or the transcriptional

networks controlling RGC subtype specification. Our combined data supports evidence of both *Atoh7*-dependent and independent populations of RGCs. The delay in RGC maturation and the failure of optic nerve formation seen in *Atoh7*-deficient retinas suggest that the earliest pathfinding RGCs are *Atoh7*-dependent. We examined expression of markers of mature RGC subtypes (Tran et al., 2019) within the developing retina and correlated expression of the transcripts with RGC pseudotime (Supplemental Figure 11) as many of the mature RGC subtype markers are not specific to RGCs. We detected expression of selective markers for a fraction of mature RGC subtypes within the E14.5 scRNA-Seq dataset. Of transcripts in which readily detectable expression was observed, many including *Igfbp4*, *Foxp1*, *Stxbp6*, *Bhlhe22*, *Penk* also display enriched expression in primary or neurogenic RPCs. Expression of some markers of RGC development and maturation *Ebf3*, *Pou4f1*, *Pou4f2*, *Prdm8* and *Slc17a6* correlated well with pseudotemporal ordering and were depleted in *Atoh7*-deficient RGCs. However, a limited number of RGC subtype markers, including *Irx3*, *Calb2*, and *Tac1* were largely absent from *Atoh7* mutant RGCs.

2.3.7 Atoh7 binds to loci associated with both RGC and photoreceptor transcripts

In order to gain insight into the function of *Atoh7* during RGC specification, we performed Cut&Run experiments (Skene and Henikoff, 2017) on E14 mouse retinas using the established *Atoh7* antibody (Miesfeld et al., 2018a) and IgG as a control. Peak calling was performed using the MACS2 pipeline (Zhang et al., 2008). High concordance of called peaks is observed between *Atoh7* Cut&Run replicates (Supplemental Figure

12A), with >3,000 shared peaks, and little enrichment of peak sequences within the IgG sample. Comparisons of *Atoh7* peaks to developmental chromatin accessibility (Aldiri et al., 2017) determined that peaks proximal to gene transcription start sites, corresponding to proximal promoters, exhibited high accessibility throughout retinal development (Supplemental figure 12B). Distal peaks, corresponding to enhancer sequences (>3kb from the transcription start sites), however, displayed the greatest accessibility during early periods of retinal development when RGCs are being generated, and when *Atoh7* expression is maximal ((Miesfeld et al., 2018a); Supplemental Figure 12B). We next determined the enrichment of DNA sequence motifs underneath called peaks using HOMER (Heinz et al., 2010). We observed a highly enriched motif (CAGCTG; $p = 1e-763$) that was present within >55% of called peaks (13.75% of background peaks; Figure 6A). Analysis of motif similarity to known transcription factor motifs indicated a high similarity of the called *Atoh7* motif to the *Atoh1* motif (CAGCTG; $p = 1e-784$; Figure 6A) and other E-Box transcription factors.

We next assigned peaks to genes using ChIPSeeker (Yu et al., 2015). Many strong peaks were located within genetic loci of transcripts with known functions during early retinal development, including *Neurod1*, *Elavl4*, *Neurog2*, *Pou6f2*, *Otx2*, *Meis2*, and *Lhx4* (Figure 6B-E; SupplementalTable 3). We also observed strong enrichment of *Atoh7* binding within the *Atoh7* proximal promoter and distal enhancer sequences (Miesfeld et al., 2020), suggestive of auto-regulation of *Atoh7* expression (Figure 6D).

In order to better understand the mechanism by which *Atoh7* regulates transcription of nearby genes, we next examined the consequence of *Atoh7* loss-of-

function on bound loci gene expression as determined by our scRNA-seq experiments in Control (WT and *Bax*^{-/-}) versus *Atoh7* Null (*Atoh7*^{-/-} and *Atoh7*^{-/-};*Bax*^{-/-}) neurogenic cells and RGCs. Our analyses indicated that many *Atoh7*-bound genes display decreased expression within *Atoh7* mutant retinas, including the RGC-enriched genes *Pou6f2*, *Elavl4*, *Isl1* and *Tubb2b* (Figure 6E). Conversely, roughly similar numbers of genes displayed increased expression in *Atoh7* mutant retinas, including neurogenic RPC-enriched transcripts *Hes6*, *Btg2*, *Neurod1*, *Neurog2*, *Sstr2*, *Pkib*, and *Bhlhe22* (Clark et al., 2019; Figure 6E). To gain further insight into the biological relevance of *Atoh7*-bound and differentially expressed transcripts, we first binned transcripts into 5 categories: 1) *Atoh7*-bound and down-regulated in *Atoh7* mutants; 2) *Atoh7*-bound and up-regulated in *Atoh7* mutants; 3) no binding, down-regulated in *Atoh7* mutants; 4) no binding and up-regulated in *Atoh7* mutants; and 5) *Atoh7*-bound but no change in expression. Following binning, we calculated z-scores of gene expression on an individual cell basis using the mouse retinal development single-cell dataset (Clark et al., 2019), and examined the enrichment of expression of binned genes within annotated cell types. Our analysis determined that *Atoh7*-bound genes that displayed decreased expression in *Atoh7* mutant retinas show enriched expression in RGCs, suggesting an active role of *Atoh7* in promoting RGC fate (Figure 6F-H). Conversely, *Atoh7*-bound genes that are upregulated in *Atoh7* mutant retinas display high expression within neurogenic cells or photoreceptor precursors, and include *Neurod1*, *Neurog2*, and *Hes6* (Figure 6F; I). We also observe *Atoh7*-binding within additional cone photoreceptor gene loci, including *Lhx4*, *Otx2*, and *Thrb* (Table 2), although these genes did not display

robust differences in gene expression between control and *Atoh7* mutant retinas. The upregulation of *Atoh7*-bound neurogenic and photoreceptor-enriched genes in *Atoh7* mutant retinas suggest that *Atoh7* actively represses photoreceptor fate during early retinogenesis, an interpretation that is supported by the observed modest increase in cone photoreceptor proportions within *Atoh7* mutant scRNA-Seq samples (Figure 4D).

2.3.8 *Galanin* is not the *Atoh7*-dependent secreted factor that promotes RGC survival and pathfinding

Our data suggest the existence of *Atoh7*-dependent factors that promote both RGC survival and pathfinding, as well as hyaloid vascular regression, in a non cell-autonomous manner. These are likely derived from *Atoh7*-expressing neurogenic RPCs and/or RGCs. Factors mediating hyaloid regression are likely to be secreted, while those regulating RGC survival could also potentially act through contact-mediated signaling. Few annotated secreted proteins show clear *Atoh7*-dependent expression in our scRNA-Seq dataset. The neuropeptide galanin (*Gal*), which is strongly expressed in both neurogenic RPCs and RGCs and is a direct target of *Atoh7* (Figure 6E) was by far the most differentially expressed secreted factor in *Atoh7*-deficient mice (Figure 4E,I, Figure 6E; Table 1). Galanin has been implicated in promoting the survival of neural precursors (Cordero-Llana et al., 2014; Holmes et al., 2000), and to be enriched in ipsilaterally projecting retinal ganglion cells (Giudice et al., 2019). However, *Gal*-deficient animals showed no differences in either the hyaloid vasculature regression or RGC density, as compared to the control animals (Supplemental Figure 13).

2.4 Discussion

It is broadly accepted that *Atoh7* acts in RPCs as a competence factor that is essential for RGC specification (Brzezinski et al., 2012; Mu et al., 2005; Yang et al., 2003; Baker and Brown, 2018). In this study, though, we show that the specification of the great majority of RGCs occurs even in the absence of *Atoh7*. While RGC specification can occur independent of *Atoh7*, *Atoh7* function is required to maintain RGC survival and proper targeting of RGC axons to the optic nerve head. Following disruption of both *Atoh7* and *Bax*, we observe only a 20% reduction in the number of RGCs relative to *Bax*-deficient controls. This compares to a greater than 95% reduction in RGC numbers in *Atoh7* mutants relative to wildtype controls. Although RGCs in *Atoh7*^{-/-};*Bax*^{-/-} retinas show severe defects in targeting the optic nerve head, they respond robustly to photoreceptor stimulation. The presence of specified RGCs in the absence of *Atoh7* helps explain long-standing, puzzling observations: 1) 45% of RGCs are not derived from *Atoh7*-expressing progenitors; 2) molecular markers of RGCs are observed at considerably higher levels during early stages of retinal development than in adults in *Atoh7*-deficient retinas; and 3) the marked increase in apoptosis in the ganglion cell layer that occurs in the absence of *Atoh7* (Brzezinski et al., 2012; Feng et al., 2010; Prasov and Glaser, 2012). Previous studies have implicated *Atoh7* as a direct upstream regulator of the essential RGC transcription factors *Brn3a*, *Brn3b*, and *Isl1*. Supporting this, an *Atoh7* hierarchy of RGC determinants, studies in which *Brn3b* and *Isl1* were inserted in place of the *Atoh7* coding sequence observed a complete rescue of normal RGC development (Wu et al., 2015). Our studies, however, indicate that when apoptosis is inhibited, *Brn3a*, *Brn3b*,

Islet1, and *Rbpms* expression is induced at near normal levels within RGCs in both E14 and adult retinas, regardless of *Atoh7* expression. Indeed, we observe that *Atoh7* binds to sites in the *Isl1* and *Pou4f1* (*Brn3a*) loci, suggesting active regulation of *Isl1* and *Brn3a* transcription by *Atoh7*. While no *Atoh7* Cut&Run peak was assigned to *Pou4f2* (*Brn3b*), two *Atoh7*-binding sites were identified in the terminal intron of *Pou4f2*-neighboring gene *Ttc29*. While further evidence is required to clearly demonstrate that *Atoh7* regulates *Pou4f2* expression via these binding sites, we observed reduced expression of *Isl1*, *Pou4f1*, and *Pou4f2* within *Atoh7*-deficient retinal cells. Therefore, we conclude that other factor(s) in addition to *Atoh7* activate expression of these genes.

The molecular mechanisms by which *Atoh7* controls axonal guidance and cell survival remain unclear. One hypothesis is that RGC axonal guidance and cell survival are linked and that loss of *Atoh7* expression fails to initiate expression of target-derived trophic cues. Because other studies have failed to detect substantial numbers of RGCs in *Atoh7*^{-/-} mice at P0 (Brown et al., 2001; Feng et al., 2010; Prasov and Glaser, 2012; Wang et al., 2001) and target derived neurotrophic factors regulate apoptosis of RGCs between P0 and P12, we suspect that *Atoh7*-induced cell survival is functioning at earlier time points than target-derived trophic signals. Additionally, as we did not observe RGC rescue within *Atoh7*^{Cre/Cre};*Bax*^{fl/fl} mice, we suggest that immature RGCs rapidly degenerate as the result of the lack of an *Atoh7*-dependent survival factor. This wave of developmental apoptosis has been observed previously, but the underlying molecular mechanisms are unknown (Farah and Easter, 2005; Frade et al., 1997; Ogilvie et al., 1998; Péquignot et al., 2003; Rodríguez-Gallardo et al., 2005; Strom and Williams, 1998;

Valenciano et al., 2009). We hypothesize that this unknown factor or factors must be produced by either *Atoh7*-expressing neurogenic RPCs or RGCs derived from these cells.

Our data also reveal a marked delay in the formation of RGCs from neurogenic RPCs in the absence of *Atoh7*. This is consistent with previous results in *Atoh7*^{-/-} retinas, where RGC formation is delayed by at least a day (Le et al., 2006; Prasov and Glaser, 2012). When *Atoh7*-dependent RGCs are rescued later in development, as seen in targeted mutants in which *Atoh7* is expressed from the endogenous *Crx* locus, the hyaloid vasculature regression was not rescued, even though a modest rescue of RGC formation is observed (Prasov and Glaser, 2012). In zebrafish retina, consistent with this result, loss of function of *atoh7* in early-stage RPCs disrupts the correct targeting of axons in later-born RGCs to the optic nerve (Pittman et al., 2008). Taken together with the fact that 45% of RGCs arising from a non-*Atoh7*-dependent lineage in mice, we hypothesize that early, pathfinding RGCs are *Atoh7*-dependent and provide both survival and guidance cues for later-born RGCs.

Since *Atoh7* was previously thought to be a master transcriptional regulator of RGC specification, strategies aimed at targeted differentiation of RGCs for therapeutic purposes have focused on using the forced expression of *Atoh7*. We, however, now appreciate RGC specification to be a far more complicated process. Although ectopic expression of *Atoh7* activates expression of RGC-specific genes in cultured retinal progenitor cells (Yao et al., 2007), induced pluripotent stem cells (Chen et al., 2010), and Müller glia-derived retinal stem cells (Song et al., 2015, 2014), it is nonetheless typically

not sufficient to drive these cells to become RGCs. This study sheds light on why this may be the case.

These findings demonstrate that additional factors act in parallel to *Atoh7* to control RGC specification. While multiple other transcription factors have been reported to regulate RGC specification -- including *Neurod1*, *Sox4*, and *Onecut2* (Jiang et al., 2013; Mao et al., 2013; Sapkota et al., 2014) -- these factors are unable to individually activate expression of *Brn3b* and *Isl1*. In *Atoh7*^{-/-};*Bax*^{-/-} RGCs, however, we observe substantially increased expression of each of these transcription factors (Figure 4E; Supplemental Figure 10), suggesting the possibility that these factors, among others, may compensate for the loss of *Atoh7*. The observations that *Atoh7* binds to target sites in the genomic loci of multiple genes that are upregulated in *Atoh7* mutant retinas -- including *Neurod1*, *Neurog2*, *Otx2*, and *Onecut2* -- suggest that *Atoh7* directly inhibit alternate mechanisms of RGC genesis. However, the identity of the non-cell-autonomous cues by which *Atoh7* regulates RGC survival, axon guidance, and hyaloid vasculature regression remain unknown. Further identification of the mechanisms regulating the interplay of intrinsic and extrinsic signals on RGC specification, survival, and maturation will help guide the future design of therapies aimed at maintaining and replacing RGCs lost due to degenerative disease.

2.5 Material and Methods

2.5.1 Mice

Animals were housed and treated in accordance with NIH and IACUC guidelines, and used protocols approved by the Johns Hopkins University Animal Care and Use Committee (Protocol numbers MO16A212). *Atoh7*^{Cre/Cre} mice are a knock-in line where Cre recombinase replaced the entire *Atoh7* gene and was a gift from Dr. Lin Gan (referred to as *Atoh7*^{-/-}) (Yang et al., 2003) (RRID:MGI:3717726). The *Bax*^{tm1Sjk/tm1Sjk} (*Bax*^{-/-}) mice containing a neomycin cassette that replaces critical exons 2-5, were purchased from The Jackson Laboratory (Knudson et al., 1995)(JAX:002994, RRID:IMSR_JAX:002994). The *Bax*^{-/-} mice are unpigmented since the *Bax* gene is linked to the *Tyrosinase* (*Tyr*) and *Pink-eyed dilution* (*p*) gene by 21cM and 5cM respectively. The conditional *Bax*^{tm2Sjk/tm2Sjk} (*Bax*^{fl/fl}) mice containing LoxP sites flanking exons 2-4, were purchased from The Jackson Laboratory (JAX:006329, RRID:IMSR_JAX:006329)(Takeuchi et al., 2005). *Atoh7*^{tTA/tTA};B&I-EE mice are a combination of two genetic strains. In the first strain (*Atoh7*^{tTA/tTA}), the tetracycline-responsive artificial transcription factor tTA replaces the *Atoh7* gene. In the absence of tetracycline, the tTA activates the tetracycline responsive element which is driving the expression of *Brn3b* and *Isl1* in the second strain (B&I-EE). Therefore, in effect the *Atoh7* promoter will drive the expression of *Brn3b* and *Isl1*. This mouse line has been previously reported to rescue all reported effects of *Atoh7* loss of function, and was a gift from Dr. Xiuqian Mu (Wu et al., 2015)(MGI:5749708 and MGI:5749713). The *Crx*>*Atoh7* mice, a transgene that expresses the full-length *Atoh7* coding sequence under

the control of the *Crx* promoter, was previously published (Prasov and Glaser, 2012)(MGI:5433215). A tdTomato Cre recombinase reporter mouse *Rosa26^{tdTomAi14}* (JAX:007914, RRID:IMSR_JAX:007914)(Madisen et al., 2010) was used to label cells in a Cre recombinase-dependent manner. The *Chx10-Cre* mouse line is a transgenic line purchased from The Jackson Laboratory, originally developed by Constance Cepko's laboratory (JAX:005105, RRID:IMSR_JAX:005105)(Rowan and Cepko, 2004), expresses Cre recombinase broadly in all retinal progenitor cells from E10-E15.5. The *Opn4^{taulacZ}* mice were used to trace the ipRGC projections to the brain (Hattar et al., 2002). Throughout the manuscript, controls are heterozygous for both *Atoh7* and *Bax* (*Atoh7^{+/-};Bax^{+/-}*), whereas *Atoh7^{-/-}* mice were also are heterozygous for *Bax* (*Atoh7^{-/-};Bax^{+/-}*).

2.5.2 Statistics

All statistical tests, apart from analysis of the scRNA-seq data, were performed in Graphpad Prism 6 (RRID:SCR_002798). The statistical tests used are listed in figure captions.

2.5.3 Immunohistochemistry

Adult retinas from P40-P200 mice were obtained by enucleating whole eyes, fixing for 30 minutes in 4% paraformaldehyde (PFA) diluted in PBS, dissecting to remove the cornea and lens, dissecting the retina from the RPE, and antibody staining proceeded in a 24-Multiwell Cell Culture Plate (Corning #353047). Retinas were blocked in 500 µl of

PBS containing 0.3% Triton X100 and 6% goat serum for 2 hours at room temperature. Several antibodies were used in this study (dilutions are between brackets): Mouse IgG1 anti-Brn3a (Millipore Cat# MAB1585 RRID:AB_94166) (1:250), Rabbit anti-RBPMS (GeneTex Cat# GTX118619 RRID:AB_10720427) (1:250), Rabbit anti Brn3b (Badea et al., 2009) (1:100), Mouse anti-Smi32 (non-phosphorylated anti-Neurofilament H (NF-H)) (BioLegend Cat# 801701 RRID:AB_2564642) (1:500), Mouse anti Neurofilament Medium (Thermo Fisher Scientific Cat# 13-0700, RRID:AB_2532998) (1:500), Chicken anti Neurofilament Heavy (Millipore Cat# AB5539, RRID:AB_11212161) (1:250), Mouse anti-GFAP (Sigma-Aldrich Cat# C9205 RRID:AB_476889) (1:1000), GS-IB4 (Molecular Probes Cat# I21411 also I21411 RRID:AB_2314662) (1:250), Rabbit anti-Pax2 (BioLegend Cat# 901001 RRID:AB_2565001) (1:100), Mouse anti-Tuj1 (R and D Systems Cat# MAB1195 RRID:AB_357520) (1:200), Rabbit anti DsRed Takara Bio (Cat# 632496, RRID:AB_10013483) (1:250), Mouse anti-Islet1 (DSHB Cat# 40.2D6 RRID:AB_528315) (1:200), and Rabbit anti-Opn4 (Advanced Targeting Systems Cat# UF006, RRID:AB_2314781) (1:500). The appropriate antibodies were diluted in blocking solution and incubated for two days at 4°C. Retinas were then washed in three changes of PBS, 15 minutes each, then placed in the appropriate Alexa Fluor secondary antibody (Invitrogen) (1:500) overnight at 4°C. Retinas were washed in 200 µl of PBS containing 1xDAPI, then washed three times in PBS for 15 minutes each, and mounted flat on slides in VectaShield (Vector Labs, RRID:AB_2336789). Regionalized dissections were done as follows; before enucleation, the most nasal part of the sclera was marked with a cauterizer. This mark was used during the dissection to make a

marking incision into the retina, following the above staining protocol. Retinas were imaged on a Zeiss LSM 700 or 800 Confocal at the Johns Hopkins University Integrated Imaging Center Core Facility (RRID:SCR_016187).

For embryonic studies, developing embryos harvested at E12.5 and E14.5 were washed in a Petri dish with sterile PBS three times for 10 minutes. Tail was used for genotyping. The heads were fixed in 4% PFA for 30 minutes and then cryoprotected in 30% sucrose at 4°C overnight, frozen in OCT, and sectioned at 18 µm thickness using a cryostat. Sections were dried at 30°C for 15 minutes and then washed 10 minutes in three changes of PBS. Sections were then blocked and stained as above in a humidified chamber overnight. Sections were then mounted and imaged as described.

2.5.4 Cell density analysis

All cell counting was done manually. To confirm the reproducibility of the cell counts, randomly selected selections from each sample were counted twice, and counts were consistently found to be essentially identical. Density was calculated as the number of cells per area. All measurements and cell number analysis were done manually in ImageJ (Fiji, RRID:SCR_002285) and Adobe Photoshop CS6 (RRID:SCR_014199).

In adult flat-mounted retinas, the density of RGCs was calculated by obtaining at least 4 representative images at 40x of 600 µm x 600 µm with 1 µm optical sections. Optical sections were projected together with maximum intensity, including cells only in the retinal layers of interest. Representative images were taken similarly across all genotypes without *a priori* knowledge of the genotype. However, some genotypes

contain marked phenotypic differences, which include a pigment mutation linked to the *Bax* locus, drastic RGC number reduction as in the *Atoh7*^{-/-}, and/or misguided axons.

Three representative areas of each retina were averaged for the density analysis

In E12.5 embryonic retinal sections, a representative confocal image was taken at 40x of 600 µm x 600 µm with optical sections of 1 µm projected together with maximum intensity. The sections chosen for analysis were all positive for Pax2+ optic nerve head cells, as the central retina contains the earliest-born RGCs. At least two sections with matching criteria were analyzed for each E12.5 embryo. Density was calculated by dividing the number of Brn3a+ RGCs and dividing by the area of the retina. To limit the analysis to the RGC neurogenic zone, we limited the quantification to the leading edge of RGC genesis. The percentage of mature Brn3a+ RGCs at E12.5 were determined by counting their number within the ganglion cell layer (GCL). The number of mature Brn3a+ RGCs was then divided by the number of total Brn3a+ RGCs in a section, and then averaged across all sections. This ratio represents the number of Brn3a+ RGCs already in the nascent ganglion cell layer versus RGCs migrating through the neuroblast layer to the ganglion cell layer.

2.5.5 Multielectrode array recordings

Mice were dark-adapted for 1-2 hours before being sacrificed and dissected under dim red light. Retinas were isolated in Ames' medium (Sigma) bubbled with 95% O₂/5% CO₂ (carbogen) at room temperature, trimmed into small rectangles, and then placed on a 6x10 perforated multielectrode array (Multichannel Systems, Tübingen, Germany),

ganglion-cell-side down. Tissue was perfused with Ames' bubbled with carbogen and kept at 32°C throughout the experiment. Data acquisition was performed using the MC_Rack software (ALA Scientific Instruments, Inc.), at a 50-kHz sampling rate. An offline spike sorter (Plexon Inc) was used for spike sorting.

UV stimuli ($I_{\text{mean}} \approx 5 \times 10^3$ photons/cm²/s, 398 nm) were generated through a modified DLP projector (HP Notebook Projection Companion Projector, Model: HSTNN-FP01) (frame rate = 60 Hz) and were delivered through an inverted microscope objective. All stimuli were programmed using the *Psychophysics Toolbox* in Matlab (The Mathworks, Natick, MA). Stimuli include: (1) 120-s, 1-Hz full-field square-wave flash (100% Michelson contrast); (2) 10-min Gaussian white noise (GWN) flickering checkerboard (pixel size = 44.77 μm); (3) 10-min spatially correlated “cloud” stimulus that was generated by low-pass filtering the GWN. The cloud stimulus introduced dark and bright areas of a range of scales within each frame, with the purpose of driving large spatial receptive fields.

The analysis was first performed using custom-written Matlab (MATLAB R2014b) codes, the results later were exported and edited in Adobe Illustrator CS6. For each cell, the peristimulus time histogram (PSTH) of responses to square-wave flash was calculated using 10-ms bins. Spatial and temporal receptive fields were identified based on noise data using a nonlinear model previously described in detail (McFarland et al., 2013; Shi et al., 2019).

Fewer cells were recorded from *Atoh7^{Cre/Cre};Bax^{-/-}* mice compared to the wildtype and *Bax^{-/-}*, as the nerve fiber layer (NFL) and retinal vasculature are improperly

developed and thus provide an insulating layer that needs to be removed in order to obtain high quality recordings. No cells were recorded from *Atoh7^{Cre/Cre}* mice, due to the >99% reduction in RGC numbers.

2.5.6 Pupillary light response (PLR)

PLR experiments were performed on mice that were dark adapted for at least 1 hour prior to any experiment. PLR was measured by gently restraining the mice by hand (without anesthesia) and exposing them to a cool white light LED bulb (6500K, light intensity: 15 W/m², MR16, SuperBrightLEDs.com) that was directed at one eye using a gooseneck arm of a dissecting microscope light source. Constriction of the pupil was recorded using a Sony Handycam camcorder (FDRAX33) from either the contralateral or ipsilateral eye to the light source. The baseline pupil size of each mouse was first recorded for at least 5 seconds using an infrared light source, following which the white LED bulb was turned on for at least 30 seconds. Video recordings were analyzed by creating screenshot images in Joint Photographic Experts Group format (jpg) of the pupil prior to and during light stimulation using VLC media player (<https://www.videolan.org/vlc/>). Pupil area was then quantified in ImageJ (Fiji, RRID:SCR_002285). To determine the relative pupil area, pupil size during the light stimulation was divided by pupil size prior to light stimulation.

2.5.7 Tissue dissociation for generation of single-cell suspensions

Eyes were enucleated from E14 time-pregnant animals and placed directly into ice-cold 1X PBS. Retinas were dissected in cold 1X PBS, and then placed into 200 µl of cold

HBSS per 2-3 retinas. Tissue dissociation was induced through the addition of an equivalent volume of Papain solution (1 ml - 700 μ l reagent grade water, 100 μ l fresh 50 mM L-Cysteine (Sigma), 100 μ l 10 mM EDTA, 10 μ l 60 mM 2-mercaptoethanol (Sigma), with Papain added to 1 mg/ml (1:10 dilution of 10 mg/ml Papain solution; Worthington)). Papain-retina mixture was placed at 37°C for 10 minutes with slight trituration every 2-3 minutes. Enzymatic dissociation was halted through the addition of 600 μ l of Neurobasal Media + 10% FBS for every 400ul of dissociation solution. DNA from lysed cells was removed using 5 μ l RNase-free DNase I (Roche) for every 1 ml dissociate and incubated at 37°C for 5 minutes, followed by slight trituration using a 1 ml pipette. Cells were pelleted after centrifugation (300 RCF for 5 minutes at 4°C), followed by resuspension in 2-3 ml of Neurobasal media supplemented with 1% FBS. The final solution was passed through a 50 μ m filter to remove cellular aggregates and undissociated debris.

2.5.8 10x Genomics Sequencing and Analysis

Single-cell RNA sequencing of dissociated retinal cells from E14 *Atoh7*^{-/+}; *Bax*^{-/-} and *Atoh7*^{-/-}; *Bax*^{-/-} was performed using 10x Genomics Chromium 3' v2 platform (PN-120223) (Pleasanton, CA), followed by sequencing using the NextSeq500 platform with default 10x sequencing parameters (R1 - 26bp; R2 - 98bp; i7 - 8bp). Single-cell analysis of the wildtype (WT) E14 developing mouse retina was obtained from previously reported samples obtained from GEO (GSE118614); data obtained using similar isolation protocols are described previously (Clark et al., 2019).

2.5.9 Gene Set Usage Pattern Discovery with scCoGAPS

CoGAPS v.3.5.6 (Sherman et al., 2019; Stein-O'Brien et al., 2019) was used to find patterns of gene set usage by Neurogenic and Retinal Ganglion Cells. The expression matrix used as input was normalized to 10,000 counts per cell, subsetted down to 5235 most highly variable genes and log2 transformed. The CoGAPS parameters used are: singleCell=TRUE, nPatterns = 30, nIterations = 50000, distributed = single-cell, sparseOptimization = True, seed = 803L, and nSets = 10. The final number of patterns stabilized at 31.

2.5.10 Identification of *Atoh7*-Dependent Genes

Data was subsetted down to neurogenic RPCs and RGCs. Monocle's differential gene test was conducted between control (WT and *Bax*^{-/-}) and *Atoh7* mutants (*Atoh7*^{-/-} *Atoh7*^{-/-}; *Bax*^{-/-}) using the following parameters:

```
differentialGeneTest(dat[genes expressed in >=10 cells], fullModelFormulaStr =  
'~(Atoh7 genotype) + Total_mRNAs', reducedModelFormulaStr =  
'~Total_mRNAs', cores=4).
```

2.5.11 Pseudotime Analysis between Genotypes

Scanpy v1.4 (Wolf et al., 2018) was first used to assign diffusion pseudotime values (Haghverdi et al., 2016) to cells in the retinal ganglion cell trajectory. Cell types included in this final dataset were restricted to retinal ganglion cells, primary RPCs, and

neurogenic RPCs. To preprocess the dataset, genes <10 counts were removed, and the expression matrix was normalized to 10,000 counts/cell and log-transformed. Highly variable genes used for ordering were identified using Scanpy's `'highly_variable_genes'` function with default parameters except `flavor='cell_ranger'` and `n_top_genes=3000`. 50 principal components were calculated using default PCA parameters with `random_state=123456`. To compute the neighborhood graph with the batch effect of genotype removed, we used BBKNN with `batch_key = "Genotype"` and `neighbors_within batch=3` (Polanski et al., 2019). 10 diffusion components were then computed and used for input to assign diffusion pseudotime values with an RPC cell as root. To find genes differentially expressed between the developmental trajectories of the WT and *Atoh7^{Cre/Cre};Bax^{-/-}* genotypes, Monocle's differential gene test (Qiu et al., 2017; Trapnell et al., 2014) was performed in R, on neurogenic RPCs and RGCs of WT and *Atoh7^{Cre/Cre};Bax^{-/-}* null genotypes:

```
differentialGeneTest(dat[genes expressed in >=10 cells], fullModelFormulaStr =
  '~sm.ns(Pseudotime,df=3)*Genotype+Total_mRNAs', reducedModelFormulaStr
  = '~sm.ns(Pseudotime,df=3)+Genotype+Total_mRNAs',cores=3)
```

2.5.12 *In situ* Hybridization

Developing embryos harvested at E14.5 were washed in Petri dishes filled with sterile DEPC-treated PBS at least three times. The head of the embryo was plunged into OCT and then immediately frozen and stored at -80°C until needed, and the tail was used for genotyping. 20 µm sections were taken using a cryostat. Sections were allowed to dry to

slides for a few hours and then were stored at -80°C until needed. *In situ* hybridization was performed as previously described (Shimogori et al., 2010).

2.5.13 Cut&Run

5 retinas from E14 C57BL6/J embryos were dissected and pooled per biological replicate and processed for Cut&Run as described in (Skene and Henikoff, 2017) with a few modifications. All steps were carried out in 0.2ml PCR tube strips and 22 µl of BioMag Concanavalin A beads (Polysciences: Cat# 86057-3) suspended in an additional 100 µl/sample of Binding Buffer (20 mM HEPES pH 7.9, 10 mM KCl, 1 mM CaCl₂, 1 mM MnCl₂). After two washes, beads were resuspended in 10 µl/sample of Binding buffer using a magnetic rack. Retinas were dissociated by pipetting and centrifuged for 3 mins at 300g in PBS at RT. Cells were then resuspended in 100 µl Buffer 1 (20mM HEPES pH 7.5, 150 mM NaCl, 0.5 mM Spermidine, 1X Millipore Protease Inhibitor Cocktail Set III: Cat# 539134) at RT. After two washes, cells were resuspended in 100 ul/sample Buffer 1 and incubated with beads for 10 min at RT. Supernatant was discarded and 50 µl cold Buffer 2 (Buffer 1, 2 mM EDTA, 0.01% Digitonin) was used to resuspend the cell/bead mix. 2 ug of Rabbit anti-Atoh7 (Novus Biologicals NBP1-88639) and 2 ug of rabbit isotype control IgG (Thermofisher cat# 02-6102) antibodies were added to the samples and incubated at 4°C overnight. Supernatant was cleared the next day and the cell/bead mix was gently resuspended in 200 µl cold Buffer 3 (Buffer 1, 0.01% Digitonin). After two washes, cell/bead mix was gently resuspended in 50 µl cold Buffer 3. 1 ul of 50X pAG-MNase was added to the cell/bead mix and incubated at RT for 10 mins. 200 µl

cold Buffer 3 was added to wash the cell/bead mix twice. Supernatant was discarded and the cell/bead mix was resuspended in 50 µl cold Buffer 3. 100 mM CaCl₂ was added and the samples were incubated on ice for 30 mins. 33 µl of Stop buffer (340 mM NaCl, 20 mM EDTA, 4 mM EGTA, 50 µg/ml RNase A, 50 µg/ml Glycogen) was added to the cell/bead mix and the samples were incubated for 10 mins at 37°C. Beads were discarded and the supernatant was used to extract DNA using Qiagen Nucleotide Removal kit as per manufacturer's specifications. DNA was eluted in 20 µl of elution buffer and sent for library preparation. Libraries were prepared per manufacturer's instructions using the KAPA HyperPrep Kit (Roche), and sequenced using the Illumina HiSeq 4000TM Sequencing system with 2x50bp sequencing parameters.

2.5.14 Cut&Run Data Processing

Pair-ended reads were aligned to mm10 with Bowtie2 v2.3.5 under parameters `--local --very-sensitive-local --no-unal --no-mixed--no-discordant --phred33 -I 10 -X 700` as described previously (Langmead and Salzberg, 2012; Meers et al., 2019). Samtools filtered out alignments with less than a 30 MAPQ score (Li et al., 2009). Picard v2.0.1 MarkDuplicates removed duplicate reads. MACS2 v2.2.7.1 called peaks with the following parameters `-t Atoh7_bed -c IgG_bed -f BED -g mm --keep-dup all -p 1e-5 -n output_file` (Zhang et al., 2008). bedtools found an overlap between the two replicates' peaks with `intersect -u -a Rep1.narrowPeak -b Rep2.narrowPeak` (Quinlan and Hall, 2010). Overlapping peaks aligning to mitochondrial or random chromosomes were removed. Homer v4.11 was used for motif discovery by using `findMotifsGenome.pl`

under default parameters (Heinz et al., 2010). In ChIPseeker v1.22.1, `annotatePeak` was used to annotate the overlapping peaks with genomic features (Yu et al., 2015).

DeepTools v3.1.0 was used to generate bigwig files for visualization (default parameters and bin size of 5bp) and for coverage heatmaps (Ramírez et al., 2016).

2.5.15 Data Availability

Single-cell RNA-sequencing processed (expression, gene (featureData), and cell (phenoData) matrices) and raw sequence information (.bam files) are available for direct download through GEO GSE148814. Atoh7 Cut&Run data is available through GEO GSE156756. The mouse developmental scRNA-seq (Clark et al., 2019) and ATAC-seq datasets were downloaded from GSE118614 and GSE102092, respectively. ATAC-seq samples were re-aligned to mm10, to conform with scRNA-seq and Cut&Run datasets using the same pipeline as described for Cut&Run samples.

2.5.16 Morris water maze

Vision was tested using a cued Morris water maze (Morris, 1984). A 150cm diameter pool was filled with water made opaque by mixing in non-toxic white tempera paint. A platform ("island", not visible from the surface of the water) was placed in one quadrant with a black and white striped 50 mL conical tube on top as a "flag". Each of six animals in a group (either *Atoh7*^{+/+}, *Atoh7*^{-/-}, or *Atoh7*^{-/-};*Bax*^{-/-}) was allowed a 90 second trial in which to swim and visually locate the island. If the animal found the island, it was allowed to remain on the island for 60 seconds before being removed from the pool. If

the animal did not locate the island, it was placed at the edge of the island, allowed to climb on, and remain on the island for 60 seconds to reinforce the island as a safe spot. Following the first trial, the island was moved to a different quadrant and animals were tested again. In total, four trials were completed with the island in four different locations.

2.5.17 Visual tracking

Visual acuity was assessed using OptoMotry (Cerebral Mechanics). Animals were placed on a platform in the viewing chamber and allowed to adapt for 10 minutes prior to testing. Testing was done for five minutes, during which the position of the animal's head was monitored to assess visual tracking. Following each tracking event, the direction and width of the grating was changed, eventually narrowing down to smaller ranges of acuity.

2.5.18 X-Gal Staining

To examine ipRGCs and projections in animals with one allele of $Opn4^{tauLacZ/+}$, adult animals were transcardially perfused with 10 mL PBS followed by 15 mL of 4% PFA. Brains were dissected and cryoprotected in 30% sucrose in PBS until the tissue had sunk in the solution (kept at 4°C) and then frozen in OCT. Cryosections (50 µm) were mounted on slides and allowed to dry up to 8 hours at room temperature. All X-Gal staining solutions were prepared according to (Mombaerts et al., 1996). Slides were rehydrated in Buffer B for 10 minutes, then immersed in Buffer C (with potassium ferricyanide, potassium ferrocyanide and 100 mg/mL X-Gal in N-N' dimethyl formamide

(DMF)) for 2 days in a dark container. On the third day, fresh Buffer C was added to the slides which were allowed to sit overnight. Following staining, slides were washed 3 times for 5 minutes in PBS, counterstained in Nuclear FastRed (diluted 1:5 in water) for 10 minutes, washed in 70% ethanol, and mounted in glycerol. Retinas were dissected in phosphate buffer and placed in X-Gal Buffer B for 10 minutes, then Buffer C for 2 days at room temperature in a dark container. On the third day, fresh Buffer C was added, and retinas were stained for an additional day. Following staining, retinas were washed 3 times for 5 minutes in PBS, washed in 70% ethanol, and flat mounted in glycerol.

2.5.19 CtB sectioning and visualization

Pulled glass needles were filled via capillary action with roughly 5 μ L of Alexa 488 conjugated Cholera toxin b subunit (CTb; Invitrogen) diluted to 5mg/mL in dH₂O. Filled needles were affixed to a Harvard Apparatus FIL-190 picospritzer. For injection, adult animals were anesthetized with 25 μ L/g body weight Avertin (1.25% tri-bromo-ethanol and 2.5% tertiary-amyl alcohol in dH₂O) and tested for alertness via toe pinch. Gentle pressure was applied behind the eye to raise it, the needles were aimed just above the skin margin, and CTb was injected in the intraocular space. Animals were allowed to recover and maintained for three days post-injection to allow the tracer to reach the distal axons tips. Following the three-day survival period, animals were transcardially perfused with 15 mL of PBS, followed by 25 mL of cold 4% PFA. Brains were dissected after perfusion and post-fixed in 4% PFA for 1 hour, then cryoprotected in 30% sucrose. Brains were frozen in OCT and sectioned at 50 μ m in a cryostat. Sections were dried overnight, fixed

in 4% PFA for 10 min, mounted in VectaShield (Vector Labs)+1.5 mg/mL DAPI and imaged on a Zeiss Imager Ml upright epifluorescence microscope (AxioVision software).

Figure 1. Brodie-Kommit et al. 2020

Figure 1. *Atoh7*-independent development of RGCs. (A-C) We observed a $25.2 \pm 0.9\%$ and $21 \pm 3\%$ reduction in RBPMS+ RGC density or Isl1+ ganglion cell layer (GCL) cells when comparing *Atoh7*^{-/-}; *Bax*^{-/-} to *Bax*^{-/-} mice. (D,E,F,G,H) Brn3a and Brn3b positive RGC density are only moderately reduced when apoptosis is blocked in *Atoh7*^{-/-}; *Bax*^{-/-} mice. (G,H) Brn3a positive RGC numbers are rescued when apoptosis is blocked in all neural retinal progenitor cells, when *Bax*^{lox/lox} is crossed to the *Chx10-Cre* transgene, which is expressed in all RPCs. However, when *Bax* is specifically removed in *Atoh7-Cre* knock-in mice, Brn3a RGCs are not rescued. Mean \pm 95% confidence intervals. Statistical significance tested by one-way ANOVA with Tukey's post test for multiple comparisons **** $p < 0.0001$.

Figure 2. Brodie-Kommit et al. 2020

Figure 2. *Atoh7* is not required for normal retinal wiring and electrophysiological function. Cells from *Atoh7*^{+/-};*Bax*^{-/-}, and *Atoh7*^{-/-};*Bax*^{-/-} mice responded to light similarly as those from wild type. (A) Two different examples, corresponding to two different sets of RGCs, per genotype of peristimulus time histogram averaged from 120 repetition of 1-Hz square wave flash: WT (upper panel), *Atoh7*^{+/-};*Bax*^{-/-} (middle), and *Atoh7*^{-/-};*Bax*^{-/-} (lower panel). (B) Distribution of the spatial receptive field measured using white noise flickering checkerboard: WT (upper, cell count = 92), *Atoh7*^{+/-};*Bax*^{-/-} (middle, cell count = 94), and *Atoh7*^{-/-};*Bax*^{-/-} (lower, cell count = 56). (C) the peristimulus time histogram (PSTH) of responses to square-wave flash was calculated using 10-ms bins. Mice assayed at P30. one-way ANOVA, followed by Dunnett's test, $p < 0.05$, between *Atoh7*^{-/-};*Bax*^{-/-} and wildtype.

Figure 3. Brodie-Kommit et al. 2020

Figure 3. RGC axon guidance and retinal vasculature development require *Atoh7*-dependent RGCs. (A,D) Smi-32 labels a subset of RGCs and their axons in an adult wildtype retina. In *Atoh7*^{-/-} mice, the Smi-32 positive RGCs have axon guidance deficits. In *Atoh7*^{-/-};*Bax*^{-/-} mice, RGCs have severe axon guidance deficits. Highlighted region (A - *Atoh7*^{-/-};*Bax*^{-/-}) is magnified in (D). (B,C) Using the contralateral pupillary light response as a readout of retina to brain connection allows the appreciation that the severe axon guidance deficits allow for some connection to the brain of the RGCs in the *Atoh7*^{-/-} or *Atoh7*^{-/-};*Bax*^{-/-} retinas. (E) It has been previously reported that the hyaloid vasculature fails to regress in *Atoh7*^{-/-} mice, thought to be due to lack of RGCs, however when the RGC numbers are rescued, in *Atoh7*^{-/-};*Bax*^{-/-} mice, the hyaloid vasculature fails to regress. However, *Atoh7* is not necessary for the hyaloid regression and retinal vasculature development, seen using *Atoh7*^{TA/TA};*B&I*^{EE} mice, which was previously seen to rescue all of the *Atoh7* null phenotypes. When *Atoh7* is rescued using the *Crx*>*Atoh7* transgene on the *Atoh7* null background, the optic nerve and 12% of RGCS are rescued (Prasov and Glaser, 2012), but the hyaloid vasculature does not regress.

Figure 4. Brodie-Kommit et al. 2020

Figure 4. Single-cell analysis of E14.5 mutant retinas and gene detection in E14 retinas. (A,B) UMAP dimension reduction of aggregated E14.5 single-cell dataset colored by (A) genotype and (B) annotated cell-type. (C) Proportions of cell types derived from each genotype. (D) Proportions of annotated cell types within each genotype. (E) Heatmap of differentially expressed transcripts across control and *Atoh7* knockout (*Atoh7*^{-/-} or *Atoh7*^{-/-};*Bax*^{-/-}) neurogenic and RGCs. (F) UMAP dimension reduction of cells colored by Scanpy pseudotime values. (G) Density of retinal ganglion cells along pseudotime by genotype. (H) Heatmap displaying differentially expressed transcripts across the interaction of pseudotime and genotype. Cells are ordered by pseudotime within each genotype. (I) Chromogenic *in situ* hybridization detecting RNA transcripts of genes from (H). Insert, depicted by a red dotted line, *Atoh7*^{-/-};*Bax*^{-/-} mice in (H) show robust galanin signal in a region outside the retina, but minimal signal in the retina (J-K). Immunohistochemistry detecting (J) RGC-specific markers: BRN3A and BRN3B and (K) pan-RGC markers: ISL1 and RBPMS in E14 retina from each genotype. Scale bar, 50 μ m. Abbreviations: RPCs, retinal progenitor cells; RGCs, retinal ganglion cells.

Figure 5. Brodie-Kommit et al. 2020

Figure 5. scCoGAPS analysis of single-cell dataset and RGC population changes in E12.5 retinas show a developmental delay in *Atoh7*^{-/-}; *Bax*^{-/-} mutants. (A) Heatmap showing the correlation between scCoGAPS pattern and cellular features. (B) Heatmap of pattern weights within individual cells ordered by pseudotime. Pattern correlations with both pseudotime and each genotype are displayed at the right. (C-E) UMAP embedding of single-cell dataset used for scCoGAPS and colored by (C) celltype or (D) genotype. (E) UMAP embedding of dataset and colored by pattern weights of scCOGAPS patterns 4, 17 and 9, displaying progressive pattern usage across RGC development.

Figure 6. Brodie-Kommit et al. 2020

Figure 6. Cut&Run analysis of Atoh7 genomic binding identifies transcriptional targets of Atoh7. (A) HOMER motif analysis of most significant *de novo* (top) enriched motifs within peaks, and similarity of enriched motifs to established transcription factor motifs (bottom). (B-D) Atoh7 and IgG Cut&Run sequencing tracks within the (B) *Neurod1*, (C) *Otx2*, and (D) Atoh7 genomic loci. Additional E14 ATAC-Seq tracks (Aldiri et al., 2017) show the alignment of Atoh7 Cut&Run peaks with open chromatin. (E) Average expression of transcripts within the control (WT and *Bax*^{-/-}) and Atoh7 Null (*Atoh7*^{-/-} or *Atoh7*^{-/-};*Bax*^{-/-}) neurogenic RPCs and RGCs. Transcripts with Atoh7 Cut&Run peaks are indicated in red. Gene names are displayed for transcripts that display both Atoh7 Cut&Run peaks and high residual to the mean expression (no change in expression). (F) Cellular enrichment of transcript expression within the developmental scRNA-Seq dataset (Clark et al., 2019) of genes with the presence/absence of Atoh7 binding and increased, decreased, or no change in expression within *Atoh7* mutant neurogenic RPCs and RGCs compared to control cells. (G-I) UMAP-dimension reductions of the developmental scRNA-Seq dataset (Clark et al., 2019) displaying the annotated (G) cell types or (H-I) normalized cellular z-scores of (H) Atoh7-bound transcripts with decreased or (I) increased expression in *Atoh7* mutants.

Supplemental Figure 1. Brodie-Kommit et al. 2020

Supplemental Figure 1. *Atoh7*-independent development of RGCs. (A,B) Whole retinal dissection showing the presence of Brn3a and Brn3b positive RGCs respectively. Notice the orientation of the retinas as marked by the orientation rose. Highlighted regions (A,B) are magnified in (A',B'). (C,D,E,F) IpRGCs are partially rescued by preventing apoptosis. (C,D) To determine if ipRGCs were undergoing apoptosis in the *Atoh7*^{-/-}, ipRGC numbers were examined in *Atoh7*^{-/-} and *Atoh7*^{-/-};*Bax*^{-/-}. ipRGCs in the *Atoh7*^{-/-};*Bax*^{-/-} were rescued to 60% of wild type levels. *Bax*^{-/-} showed a 202±9% increase in ipRGCs compared to controls, similar to what has been reported for other RGCs in the *Bax*^{-/-} knockout. (E,F) To determine if ipRGCs were generated in development in *Atoh7*^{-/-} mice, I examined E16 and P0 timepoints using the *Opn4*^{tauLacZ} marker. At both E16 and P0, a 90% deficit of ipRGCs was observed. Mean ± 95% confidence intervals. Statistical significance tested by one-way ANOVA with Tukey's post test for multiple comparisons ** p=0.0052, **** p < 0.0001.

Supplemental Figure 2. Brodie-Kommit et al. 2020

Supplemental Figure 2. *Atoh7^{Cre};R26^{tdTomato}* lineage labeling. (A,B) A similar percent of RGCs are of the *Atoh7* lineage in both wildtype and *Atoh7^{-/-};Bax^{-/-}* mice. Yellow arrows highlight Brn3a⁺ and *Atoh7*-expressing RPC-derived RGCs while blue arrows highlight non-Brn3a⁺ cells in the GCL (ganglion cell layer). (C) *Atoh7^{Cre};R26^{tdTomato}* labels cells of most cell types in the retina in all genotypes examined. Abbreviations: GCL, INL (inner nuclear layer), ONL (outer nuclear layer).

Supplemental Figure 3. Brodie-Kommit et al. 2020

Supplemental Figure 3. Detailed response to light of individual RGCs in *Atoh7^{-/-};Bax^{-/-}* mice. Peristimulus time histogram averaged from 120 repetition of 1-Hz square wave flash of every RGC recorded from in *Atoh7^{-/-};Bax^{-/-}* mice. The red line represents the transition from Light on to Light off in the square wave light flash.

Supplemental Figure 4. Brodie-Kommit et al. 2020

Supplemental Figure 4. RGC axon guidance requires *Atoh7*-dependent RGCs. Similar results seen with Tuj1 (A), NFM, and NFH (B) immunostaining as seen with Smi-32 staining. (C) More examples of orientation preserved dissection of whole retinas of all four genotypes and stained with an antibody to Smi-32, notice the orientation of the retinas as marked by the orientation rose.

Supplemental Figure 5. Brodie-Kommit et al. 2020

Supplemental Figure 7. Traces of Pupillary light reflex (PLR) of individual mice before and after light stimulus for contralateral (A) and ipsilateral (D) recordings. *Bax*^{-/-} and *Atoh7*^{-/-};*Bax*^{-/-} mice lack retinal pigmentation therefore their pupils are outlined for clarity. Analysis of the relative pupil area of all of the PLR responses between genotypes for contralateral (B) and ipsilateral (C). Mean \pm 95% confidence intervals.

Supplemental Figure 6. Brodie-Kommit et al. 2020

Supplemental Figure 6. During early development, E12.5, *Atoh7^{-/-};Bax^{-/-}* mice have both fewer Brn3a positive RGCs and mature RGCs. (A) Pax2 antibody staining was used to help find the central retina to make sure the earliest born RGCs in the central retina were fully sampled. (B) Quantification of the retinal images with the black bars representing density and the red bar plotted on the right side representing the percent of mature RGCs. Mean ± 95% confidence intervals. Statistical Significance tested by unpaired t test ** p = 0.0099 **** p < 0.0001. Abbreviations: RGCs, retinal ganglion cells; GCL, ganglion cell layer.

Supplemental Figure 7. Brodie-Kommit et al. 2020

Supplemental Figure 7. RGCs in *Atoh7^{-/-};Bax^{-/-}* mice do not sustain visual tasks. In the virtual optometer, animals visually track a moving grating of varied widths. (A) Only wild type animals were able to track gratings with an acuity of 0.4 cycles/degree. In the cued Morris Water Maze (B) animals locate a marked platform to escape the water. In four successive trials, most wild type animals learned to locate the platform relatively quickly. (C) ipRGC projections do not reach the brain in *Atoh7^{-/-};Bax^{-/-}* mice. The projections of ipRGCs were genetically labeled with the tauLacZ marker (depicted here as Opn4+/-) in the *Atoh7^{-/-};Bax^{-/-}* background. Robust innervation is revealed by X-Gal staining in the control while the *Atoh7^{-/-};Bax^{-/-}* mice do not show innervation (target nuclei outlined in red). (n=3, scale bars = 100mm). (D) Fluorescently conjugated Cholera toxin b labels RGC projections. Non-image forming (SCN, OPN) and image-forming targets (LGN, SC) do not receive retinal innervation in *Atoh7^{-/-}* or *Atoh7^{-/-};Bax^{-/-}* mice. Yellow outlines depict targets; All scale bars 100mm, n=3 per genotype. Mean \pm 95% confidence intervals. Statistical significance tested by one-way ANOVA with Tukey's post test for multiple comparisons * p=0.0386, **** p < 0.0001. Abbreviations: SCN: Suprachiasmatic nucleus, OPN: Olivary Pretectal Nucleus, LGN: Lateral geniculate nucleus, SC: Superior colliculus.

Supplemental Figure 8. Brodie-Kommit et al. 2020

Supplemental Figure 8. (A) Table of scRNA-Seq statistics for each sample. (B-C) Boxplots of the number of (B) Expressed Genes and (C) Unique molecular identifier (UMI) or transcript counts within each cell. (D) UMAP dimension reduction of the aggregate single cell datasets with individual cells colored by originating sample identity. (E) UMAP dimension reductions displaying the subset of cells corresponding to each genotype (top) and the cell type annotations (bottom) of the corresponding cells. (F) Cell type annotations of cells within each scRNA-Seq sample. (G) Heatmap of known cell type markers within annotated cell types.

Supplemental Figure 9. Brodie-Kommit et al. 2020

Supplemental Figure 9. (A) Dotplot of a subset of marker genes used to determine cell type annotations of clusters within UMAP dimension reduction space. Color of the circle corresponds to the log() of the mean expression of individual transcripts within cells of each cluster. Size of the circles corresponds to the percentage of cells within the cluster that had at least one transcript detected. (B) Heatmap of the cell type enrichment of *Atoh7*-dependent, differentially expressed transcripts across wildtype mouse retinal development (E11-P14) as assayed by Clark et al., 2019.

Curriculum vitae

Justin Brodie-Kommit

Born on March 1, 1990 in Boston, Massachusetts, USA

Johns Hopkins University
Biology Department
226 Mudd Hall
Baltimore, MD 21218
Jbrodie3@jh.edu

3714 Hickory Ave
Baltimore, MD 21211
(978)201-9007
Justin@JustinBK.com

Education and Research Experience

Postdoctoral Fellow 2019-Present
Johns Hopkins University, Baltimore, MD
Laboratory of Samer Hattar, PhD & Haiqing Zhao, PhD

PhD Candidate in Biology 2012-2019
Graduate program in Cellular, Molecular, Developmental Biology, and Biophysics
Johns Hopkins University, Baltimore, MD
Laboratory of Samer Hattar, PhD
Thesis: "Atoh7-independent specification of retinal ganglion cell identity"

B.S. in Biochemistry/Cell Biology, Minor in Philosophy 2008-2012
Bucknell University, Lewisburg, PA
Laboratory of Emily Stowe, PhD

Pre-Doctoral Research Intern Jun-Aug 2011
National Cancer Institute, Frederick, MD
Laboratory of Alan Perantoni, PhD

Teaching Assistantships at Johns Hopkins University

Introduction to the Human Brain Spring 2018, 2019
Cell Biology Lecture Teaching Assistant Spring 2016, 2017
Biochemistry Lecture Teaching Assistant Fall 2016, 2018
Genetics Lecture Teaching Assistant Fall 2015, 2017, 2018
Developmental Biology Lab Teaching Assistant Spring 2014
Genetics Lab Teaching Assistant Fall 2013

Mentoring Experience

Undergraduate mentoring 2014-2016
Johns Hopkins University, Baltimore, MD
Laboratory of Samer Hattar, PhD

Publications

Invited Presentation

“Understanding the role of Math5 (Atoh7) in Retinal Ganglion Cell specification.” Society for Developmental Biology 76th Annual Meeting, Neuro(R)evolution Satellite Symposium. 2017. Minneapolis, MN.

Poster Presentations

- Brodie-Kommit, J. Shi H., Clark B., Wu F., Schmidt TM, Mu X., Blackshaw S., Singer J, Hattar S. (2018) Understanding the role of Math5 (Atoh7) in Retinal Ganglion Cell specification. Genetics, Genomics, and Evolution of the Eye, Visual System Development, Gordon Research Conference, Barga, Italy
- Brodie-Kommit, J. Shi H., Clark B., Wu F., Schmidt TM, Mu X., Blackshaw S., Singer J, Hattar S. (2018) Understanding the role of Math5 (Atoh7) in Retinal Ganglion Cell specification. Development of the Visual System: Cells, Circuits, and Disease, Visual System Development, Gordon Research Seminar, Barga, Italy.
- Brodie-Kommit, J. Shi H., Clark B., Wu F., Schmidt TM, Mu X., Blackshaw S., Singer J, Hattar S. (2017) Overturning the role of Math5 (Atoh7) in Retinal Ganglion Cell specification. Society for Neuroscience Annual Meeting, Washington DC.
- Brodie-Kommit, J. Shi H., Clark B., Wu F., Schmidt TM, Mu X., Blackshaw S., Singer J, Hattar S. (2017) Overturning the role of Math5 (Atoh7) in Retinal Ganglion Cell specification. Society for Developmental Biology 76th Annual Meeting, Minneapolis, MN.
- Brodie-Kommit, J. Shi H., Wu F., Schmidt TM, Mu X., Singer J, Hattar S. (2017) Overturning the role of Math5 (Atoh7) in Retinal Ganglion Cell specification. Association for Research in Vision and Ophthalmology Annual Meeting, Baltimore, MD.
- Brodie-Kommit, J. Shi H., Wu F., Schmidt TM, Mu X., Singer J, Hattar S. (2016) Math5 (Atoh7) is not necessary for the specification of a subset of retinal ganglion cells. Gordon Research Conference on the Circuits, Evolution and Disease in Visual System Development, West Dover, VT.
- Brodie-Kommit, J. Shi H., Wu F., Schmidt TM, Mu X., Singer J, Hattar S. (2016) Math5 (Atoh7) is not necessary for the specification of a subset of retinal ganglion cells. Gordon Research Seminar on the Fundamental Mechanisms Underlying Health and Disease in Visual System Development, West Dover, VT.
- Brodie-Kommit J, Hattar S, Schmidt TM (2014) The Transcription Factor Math5 is Not Required for Specification of Distinct Subtypes of Retinal Ganglion Cells. Federation of American Societies for Experimental Biology Conference on Retinal Neurobiology and Visual Processing, Saxtons River, VT

- Brodie-Kommit J, Schmidt TM, Hattar S (2014) The Transcription Factor Math5 is Not Required for Specification of A Subset of Retinal Ganglion Cells. Association for Research in Vision and Ophthalmology Annual Meeting, Orlando, FL.
- Brodie-Kommit J, Stowe-Evans E (2011) Characterization of chromatic adaptation of *Gloeotrichia* sp. UTEX 583. Experimental Biology Conference, Washington DC
- Brodie-Kommit J, Stowe WC, Stowe-Evans E (2010) Analysis of Chromatic Adaptation in *Gloeotrichia* sp. UTEX 583. American Society for Microbiology regional meeting in Clearfield, PA

Awards

Society for Developmental Biology Best Graduate Poster Competition, Honorable Mention at 2017 Society for Developmental Biology Annual Meeting in Minneapolis, MN
 Society for Developmental Biology Student/Postdoc Travel Award for the 2017 Society for Developmental Biology Annual Meeting in Minneapolis, MN
 National Eye Institute Travel Grant for the 2017 annual Association for Research in Vision and Ophthalmology (ARVO) Conference in Baltimore, MD
 Association for Research in Vision and Ophthalmology (ARVO) Member in Training 1st Place Poster Award in the Visual Neuroscience section at 2014 annual meeting in Orlando, FL
 Victor Corces Teaching Award for excellence while a teaching assistant for Genetics in Fall 2013
 American Society for Microbiology 2nd place poster award in the Molecular category during the 2010 regional meeting in Clearfield, PA

Professional Memberships

Society for Neuroscience	2017, 2019, 2020
Association for Research in Vision and Ophthalmology	2014, 2017
Society for Developmental Biology	2017
American Society for Microbiology	2011
